ABSTRACT: In an extension of the minimal supersymmetric standard model (popularly known as the $\mu\nu$ SSM), three right handed neutrino superfields are introduced to solve the μ -problem and to accommodate the non-vanishing neutrino masses and mixing. Neutrino masses at the tree level are generated through R -parity violation and seesaw mechanism. We have analyzed the full effect of one-loop contributions to the neutrino mass matrix. We show that the current three flavour global neutrino data can be accommodated in the $\mu\nu$ SSM, for both the tree level and one-loop corrected analyses. We find that it is relatively easier to accommodate the normal hierarchical mass pattern compared to the inverted hierarchical or quasi-degenerate case, when one-loop corrections are included.

1. Introduction

Despite its stupendous success in explaining elementary particle interactions, the celebrated standard model (SM) of particle physics suffers from some shortcomings, both theoretical and experimental. On the experimental side, explaining the masses and the mixing pattern of neutrinos is a task in which the SM is an apparent failure. The neutrino sector, therefore, is a natural testing ground for most proposals for going beyond the SM.

Supersymmetry (SUSY) is a rather popular choice for new physics. The minimal supersymmetric version of the SM (MSSM) provides a natural solution to the so-called “gauge-hierarchy problem” through the introduction of superpartners of SM-particles. However, MSSM itself is not free of drawbacks. One of these is the so-called μ -problem [1], which essentially means our lack of understanding as to why the higgsino mass parameter, a SUSY invariant quantity, has to be around the SUSY breaking scale. This problem can be solved in the next-to minimal supersymmetric version of the standard model (NMSSM), where, unlike in the MSSM, the μ -term becomes a derived quantity with the right order of magnitude.

Unfortunately, neither the MSSM nor NMSSM by itself can explain the observed pattern of neutrino masses and mixing, on which definite guidelines have been set down by existing data [2, 3]. The situation becomes different if one allows violation of the discrete symmetry known as R -parity (R_p) [4–12], defined as $R_p = (-1)^{L+3B+2S}$, where $L(B)$ is the lepton(baryon) number and S is the spin, of a particle. Neutrino masses and mixing have been analyzed in these models under various assumptions, both at the tree level and by taking loop-induced effects into account. Neutrino mass generation in variants of R_p violating MSSM have been addressed in refs. [13–62]. Such extensive study has established R_p -violation to be as potent in neutrino mass generation as the well-known seesaw mechanism [63–67] which requires introduction of gauge singlet neutrino superfields.

R -parity violation, in both the contexts of accelerator phenomenology and, for example, neutrino mass generation, have been extensively studied in various scenarios, especially in its L -violating incarnation. Thus one has so-called trilinear R -parity violation driven by the λ_{ijk} or λ'_{ijk} -type terms in the superpotential. In addition to new signals induced by three-body decays of the lightest neutralino, neutrino masses are generated through loop effects in such scenarios [13–20]. Then one can have R -parity broken by bilinear terms [21–58] of the type $\epsilon_i L_i H_2$. One here notices remarkable features like (a) non-zero vacuum expectation values for sneutrinos, and (b) the mixing between neutrinos and neutralinos as well as charged leptons and charginos. Such a scenario generates one neutrino mass at the tree level while the other mass(es) need to be generated via loop effects [39–51]. The characteristic signal consists in final state with comparable numbers of muons and taus at high energy colliders [52–58].

Bilinear R -parity violation, is also linked with spontaneous L -breaking [10, 59–62] via a singlet sneutrino vacuum expectation value (VEV). Such an effect triggers terms of the type $\epsilon_i L_i H_2$ in the superpotential, and also leaves as its footprint a Majoron which has its own experimental signature [68–70], being an additional source of missing energy.

In the backdrop of such a rich phenomenology of relatively minimalistic R -parity break-

ing models, further embellishments on the minimal scenarios have also been studied, often with some specific goals. A proposal for neutrino mass generation together with a solution to the μ -problem, with the same set of gauge-singlet right chiral neutrino superfields, has been advocated in [71]. This is popularly known as $\mu\nu$ SSM. Following this proposal, the scalar sector and the parameter space of $\mu\nu$ SSM was studied in great detail in [72]. In $\mu\nu$ SSM, the three generations of SM-neutrinos can acquire masses through a TeV-scale seesaw mechanism, with both neutralinos and heavy neutrinos participating in the process [73]. Issues of neutrino mass generation and the μ -problem can also be found in some recent works [74–78].

A comprehensive analytical study of mass generation of light neutrinos in $\mu\nu$ SSM, accompanied by necessary numerical analysis, has been discussed in ref. [73]. In this work, neutrino masses and mixing, consistent with the three flavour global neutrino data, are reproduced even with the simplistic choice of flavour diagonal neutrino Yukawa couplings (Y_ν^{ii}). Decay modes of the lightest neutralino into two-body final states ($Z^0\nu_\ell$, $W^\pm\ell$) have also been considered for various compositions of the lightest neutralino. In addition, correlations between neutrino mixing angles, and ratio of the decay branching ratios into $W^\pm$ -charged lepton are studied there as a possible test of this model at the Large Hadron Collider (LHC).

Among other related studies of importance, neutrino mass generation and collider aspects of this model, with one and two generation(s) of the right handed neutrinos, have been addressed in ref. [79]. For one right handed neutrino, neutrino mass generation has been studied there upto one-loop level. Decays of the lightest neutralino into all possible final states are also studied in this reference. Constraints on complex vacuum expectation values (VEVs) from electroweak symmetry breaking (EWSB), and its consequence on the neutrino sector are studied in ref. [80], where issues concerning spontaneous CP-violation are also addressed. The role of gravitino as a dark matter candidate in this model was studied in ref. [81]. This paper also highlighted the prospects of detecting gamma rays from decaying gravitinos. For an overview of various other aspects of $\mu\nu$ SSM, see the recent review [82].

In this work, we study in detail the effect of radiative corrections, upto one-loop, to the neutrino masses and mixing, consistent with the three flavour global data [2, 3]. As mentioned before, a similar study, but with just one generation of right handed neutrino, was carried out in [79]. However, a full study addressing both neutrino masses and the bilarge mixing pattern, with a complete set of one-loop corrections with all three generations of left and right handed neutrinos, has so far been lacking. This is exactly what we attempt in the present work. We also perform a systematic study to identify the crucial parameters of the model, which control the tree level or the one-loop dominance in the neutrino sector.

As shown in Ref. [73, 79], a very attractive feature of this model is that the ratios of certain decay branching ratios show very nice correlation with the neutrino mixing angles. This is very similar to bilinear R-parity violating models [52, 53, 56]. Nevertheless, one should note certain differences in these two cases. In $\mu\nu$ SSM lepton number is broken explicitly in the superpotential by terms which are trilinear as well as linear in singlet

neutrino superfields. In addition to that there are lepton number conserving terms involving the singlet neutrino superfields with dimensionless neutrino Yukawa couplings. After the electroweak symmetry breaking these terms can generate the effective bilinear R-parity violating terms as well as the $\Delta L = 2$ Majorana mass terms for the singlet neutrinos in the superpotential. In general, there are corresponding soft supersymmetry breaking terms in the scalar potential. Thus the parameter space of this model is much larger compared to the bilinear R-parity violating model. Hence, in general, one would not expect a very tight correlation between the neutrino mixing angles and the ratios of decay branching ratios of the LSP. However, under certain simplifying assumptions (as discussed in Sec. 3.2), one can reduce the number of free parameters and in those cases it is possible that the above correlations reappear. As mentioned earlier, this has been studied in great detail for the two body $\ell - W$ final states in [73] and for all possible two and three body final states in [79]. Let us note in passing that such a nice correlation is lost in the general scenario of bilinear-plus-trilinear R-parity violation [53].

Another important difference between $\mu\nu$ SSM and the bilinear R-parity violating model in the context of the decay of the LSP (assumed to be the lightest neutralino in this case) is that in $\mu\nu$ SSM the lightest neutralino can have a significant singlet neutrino (ν^c) contribution. In this case, the correlation between neutrino mixing angles and decay branching ratios of the LSP is different [73, 79] compared to the cases when the dominant component of the LSP is either a bino, or a higgsino or a Wino. This gives us a possibility of distinguishing between different R-parity violating models through the observation of the decay branching ratios of the LSP in collider experiments [73, 79]. In addition, the decay of the lightest neutralino will show displaced vertices in collider experiments and when the lightest neutralino is predominantly a singlet neutrino, the decay length can be of the order of several meters for a lightest neutralino mass in the neighbourhood of 50 GeV [79]. This is very different from the bilinear R-parity violating model where for a Bino LSP of similar mass the decay length is less than or of the order of a meter or so [56].

The paper is organized as follows. We start with a brief introduction to the model in section 2 and discuss the electroweak symmetry breaking conditions. The neutrino sector is discussed in section 3 in details, accompanied with necessary analytical results. We discuss the observed pattern of neutrino masses and mixing upto one-loop corrections. We present a comprehensive discussion on the results of our numerical analysis of neutrino masses and mixing in section 4. The three broad scenarios, namely, normal hierarchy, inverted hierarchy, and quasi-degenerate neutrinos, are taken up in turn in this section. We conclude in section 5. Various technical details, such as different mass matrices, couplings, Feynman rules and the expressions for one-loop contributions are relegated to the appendices.

2. Electroweak symmetry breaking in $\mu\nu$ SSM

The superpotential for $\mu\nu$ SSM includes three gauge-singlet right handed neutrino superfields ($\hat{\nu}_i^c$ ($i = e, \mu, \tau$)) along with the usual MSSM superfields. The superpotential of

$\mu\nu$ SSM along the lines of ref. [71] is

$$W = \epsilon_{ab}(Y_u^{ij}\hat{H}_2^b\hat{Q}_i^a\hat{u}_j^c + Y_d^{ij}\hat{H}_1^a\hat{Q}_i^b\hat{d}_j^c + Y_e^{ij}\hat{H}_1^a\hat{L}_i^b\hat{e}_j^c + Y_\nu^{ij}\hat{H}_2^b\hat{L}_i^a\hat{\nu}_j^c) \\ - \epsilon_{ab}\lambda^i\hat{\nu}_i^c\hat{H}_1^a\hat{H}_2^b + \frac{1}{3}\kappa^{ijk}\hat{\nu}_i^c\hat{\nu}_j^c\hat{\nu}_k^c, \quad (2.1)$$

where $\hat{H}_1$ and $\hat{H}_2$ are the Higgs superfields that have Yukawa couplings with down- and up-type quarks, respectively. $\hat{Q}_i$ are doublet quark superfields, $\hat{u}_j^c$ ($\hat{d}_j^c$) are singlet up-type (down-type) quark superfields, $\hat{L}_i$ are doublet lepton superfields, and $\hat{e}_j^c$ are singlet charged lepton superfields. The absence of any bilinear terms in the superpotential is ensured by imposing a Z_3 symmetry (which is also used in case of NMSSM). The effective μ -term is given by $\mu = \sum \lambda^i v_i^c$, where v_i^c is the VEV obtained by the ' i '-th right handed sneutrino (scalar component of $\hat{\nu}_i^c$) after EWSB. The characteristic bilinear R_p violating terms ($\varepsilon_i \hat{L}_i \hat{H}_2$) appear in a similar way after the EWSB. These terms are given by $\varepsilon^i = \sum Y_\nu^{ij} v_j^c$. The last two terms of the superpotential (see eq.(2.1)) violate R_p through L-violation. The last term, with the coefficient κ^{ijk} , is included in order to avoid an unacceptable axion associated to the breaking of a global U(1) symmetry [83]. This term generates effective Majorana masses for the singlet neutrinos at the electroweak scale.

It has been shown earlier [71–73] that the above R_p -violating superpotential (see eq.(2.1)) provides the minimal structure, sufficient for both generating a neutrino mass pattern, and offering a solution to the μ -problem. There have been studies [84,85] on R_p -violating scenarios including right handed neutrinos, which use a subset of this minimal superpotential, but without any attempt to address the μ -problem. Similar remarks apply to earlier works [86] aimed at explaining the baryon asymmetry of the universe through leptogenesis, using the term $\hat{\nu}^c \hat{H}_1 \hat{H}_2$.

The frequently discussed trilinear L -violating terms, driven by the well-known λ - and λ' -type couplings, need not appear explicitly in this model. The reason is the following; the above superpotential, as has already been stated, can lead to 'bilinear' terms of the form $L_i H_2$ once the right sneutrinos acquire VEV, and, once such terms arise, they can effectively lead to the λ and λ' -type terms [30,31]. Here, as a digression, let us mention that the spontaneous breakdown of the Z_3 symmetry through right-sneutrino VEV can in general lead to the formulation of domain walls [87]. The associated problems can, however, be ameliorated through well-known methods [88].

Coming back to $\mu\nu$ SSM, if we confine ourselves to the framework of supergravity mediated supersymmetry breaking, the Lagrangian $\mathcal{L}_{\text{soft}}$, containing the soft-supersymmetry-breaking terms is given by

$$-\mathcal{L}_{\text{soft}} = (m_Q^2)^{ij}\tilde{Q}_i^{a*}\tilde{Q}_j^a + (m_{u^c}^2)^{ij}\tilde{u}_i^{c*}\tilde{u}_j^c + (m_{d^c}^2)^{ij}\tilde{d}_i^{c*}\tilde{d}_j^c + (m_L^2)^{ij}\tilde{L}_i^{a*}\tilde{L}_j^a \\ + (m_{e^c}^2)^{ij}\tilde{e}_i^{c*}\tilde{e}_j^c + m_{H_1}^2 H_1^{a*} H_1^a + m_{H_2}^2 H_2^{a*} H_2^a + (m_{\nu^c}^2)^{ij}\tilde{\nu}_i^{c*}\tilde{\nu}_j^c \\ + \epsilon_{ab} \left[(A_u Y_u)^{ij} H_2^b \tilde{Q}_i^a \tilde{u}_j^c + (A_d Y_d)^{ij} H_1^a \tilde{Q}_i^b \tilde{d}_j^c + (A_e Y_e)^{ij} H_1^a \tilde{L}_i^b \tilde{e}_j^c + \text{H.c.} \right] \\ + \left[\epsilon_{ab} (A_\nu Y_\nu)^{ij} H_2^b \tilde{L}_i^a \tilde{\nu}_j^c - \epsilon_{ab} (A_\lambda \lambda)^i \tilde{\nu}_i^c H_1^a H_2^b + \frac{1}{3} (A_\kappa \kappa)^{ijk} \tilde{\nu}_i^c \tilde{\nu}_j^c \tilde{\nu}_k^c + \text{H.c.} \right] \\ - \frac{1}{2} \left(M_3 \tilde{\lambda}_3 \tilde{\lambda}_3 + M_2 \tilde{\lambda}_2 \tilde{\lambda}_2 + M_1 \tilde{\lambda}_1 \tilde{\lambda}_1 + \text{H.c.} \right). \quad (2.2)$$

The first two lines of eq.(2.2) consist of squared-mass terms of squarks, sleptons and Higgses, the next two lines contain the trilinear scalar couplings, while in the last line, M_3, M_2 , and M_1 represent the Majorana masses corresponding to $SU(3)$, $SU(2)$ and $U(1)$ gauginos $\tilde{\lambda}_3, \tilde{\lambda}_2$, and $\tilde{\lambda}_1$, respectively. The tree-level scalar potential receives the usual D and F term contributions, in addition to the terms from $\mathcal{L}_{\text{soft}}$.

We adhere to the CP -preserving case, so that only the real parts of the neutral scalar fields develop, in general, the following VEVs,

$$\langle H_1^0 \rangle = v_1, \quad \langle H_2^0 \rangle = v_2, \quad \langle \tilde{\nu}_i \rangle = v'_i, \quad \langle \tilde{\nu}_i^c \rangle = v_i^c. \quad (2.3)$$

The tree level neutral scalar potential looks like

$$\begin{aligned} \langle V_{\text{neutral}} \rangle = & \left| \sum_{i,j} Y_\nu^{ij} v'_i v_j^c - \sum_i \lambda^i v_i^c v_1 \right|^2 + \sum_j \left| \sum_i Y_\nu^{ij} v'_i v_2 - \lambda^j v_1 v_2 + \sum_{i,k} \kappa^{ijk} v_i^c v_k^c \right|^2 \\ & + \left| \sum_i \lambda^i v_i^c v_2 \right|^2 + \sum_i \left| \sum_j Y_\nu^{ij} v_2 v_j^c \right|^2 + \left(\frac{g_1^2 + g_2^2}{8} \right) \left[\sum_i |v'_i|^2 + |v_1|^2 - |v_2|^2 \right]^2 \\ & + \left[\sum_{i,j} (A_\nu Y_\nu)^{ij} v'_i v_j^c v_2 - \sum_i (A_\lambda \lambda)^i v_i^c v_1 v_2 + \sum_{i,j,k} \frac{1}{3} (A_\kappa \kappa)^{ijk} v_i^c v_j^c v_k^c + \text{H.c.} \right] \\ & + \sum_{i,j} (m_L^2)^{ij} v_i'^* v_j' + \sum_{i,j} (m_{\tilde{\nu}^c}^2)^{ij} v_i^c v_j^c + m_{H_2}^2 |v_2|^2 + m_{H_1}^2 |v_1|^2. \end{aligned} \quad (2.4)$$

It is important to notice that the potential is bounded from below as the coefficients of the fourth power of all the eight superfields are positive. We further assume that all the parameters present in the scalar potential are real. From eq.(2.4), the minimization conditions in terms of v_i^c, v'_i, v_2, v_1 can be derived (the equations are provided in appendix A). The minimization conditions for $\mu\nu$ SSM have also been addressed in [72, 73, 79]. Similar conditions, but for complex VEVs, have been discussed in ref. [80]. Note that in order to generate correct order of magnitudes for the light neutrino masses through the TeV scale seesaw mechanism, one requires smaller values for neutrino Yukawa couplings ($Y_\nu^{ij} \sim \mathcal{O}(10^{-6})$) and left handed sneutrino VEVs ($v'_i \sim \mathcal{O}(10^{-4})$ GeV).

3. The neutrino sector

3.1 Neutral fermions

In this model, three $SU(2)_L$ doublet neutrinos (ν_i) and three gauge-singlet right handed neutrinos (ν_i^c) mix with the MSSM neutralinos (two neutral gauginos and two neutral higgsinos) due to L-violating interactions (see eq.(2.1)). The resulting neutralino mass matrix therefore is of dimension 10×10 . The mixing among various current eigenstates are governed by the VEVs of various neutral scalar fields (namely, $H_1^0, H_2^0, \tilde{\nu}_i, \tilde{\nu}_i^c$). This matrix has been addressed in refs. [71–73, 79] for real VEVs, and in ref. [80] for complex VEVs.

In the weak interaction basis, defined by,

$$\Psi^{0T} = \left(\widetilde{B}^0, \widetilde{W}_3^0, \widetilde{H}_1^0, \widetilde{H}_2^0, \nu_e^c, \nu_\mu^c, \nu_\tau^c, \nu_e, \nu_\mu, \nu_\tau \right), \quad (3.1)$$

the neutral fermion mass term in the Lagrangian is of the form

$$\mathcal{L}_{neutral}^{mass} = -\frac{1}{2} \Psi^{0T} \mathcal{M}_n \Psi^0 + \text{H.c.}, \quad (3.2)$$

where $\mathcal{M}_n$ is the 10×10 modified neutralino mass matrix, and is given by

$$\mathcal{M}_n = \begin{pmatrix} M_{7 \times 7} & m_{3 \times 7}^T \\ m_{3 \times 7} & 0_{3 \times 3} \end{pmatrix}. \quad (3.3)$$

Here, using eq.(A.5),

$$M_{7 \times 7} = \begin{pmatrix} M_1 & 0 & -\frac{g_1}{\sqrt{2}}v_1 & \frac{g_1}{\sqrt{2}}v_2 & 0 & 0 & 0 \\ 0 & M_2 & \frac{g_2}{\sqrt{2}}v_1 & -\frac{g_2}{\sqrt{2}}v_2 & 0 & 0 & 0 \\ -\frac{g_1}{\sqrt{2}}v_1 & \frac{g_2}{\sqrt{2}}v_1 & 0 & -\mu & -\lambda^e v_2 & -\lambda^\mu v_2 & -\lambda^\tau v_2 \\ \frac{g_1}{\sqrt{2}}v_2 & -\frac{g_2}{\sqrt{2}}v_2 & -\mu & 0 & \rho^e & \rho^\mu & \rho^\tau \\ 0 & 0 & -\lambda^e v_2 & \rho^e & 2u_c^{ee} & 2u_c^{e\mu} & 2u_c^{e\tau} \\ 0 & 0 & -\lambda^\mu v_2 & \rho^\mu & 2u_c^{\mu e} & 2u_c^{\mu\mu} & 2u_c^{\mu\tau} \\ 0 & 0 & -\lambda^\tau v_2 & \rho^\tau & 2u_c^{\tau e} & 2u_c^{\tau\mu} & 2u_c^{\tau\tau} \end{pmatrix}, \quad (3.4)$$

and

$$m_{3 \times 7} = \begin{pmatrix} -\frac{g_1}{\sqrt{2}}v'_e & \frac{g_2}{\sqrt{2}}v'_e & 0 & r_c^e & Y_\nu^{ee}v_2 & Y_\nu^{e\mu}v_2 & Y_\nu^{e\tau}v_2 \\ -\frac{g_1}{\sqrt{2}}v'_\mu & \frac{g_2}{\sqrt{2}}v'_\mu & 0 & r_c^\mu & Y_\nu^{\mu e}v_2 & Y_\nu^{\mu\mu}v_2 & Y_\nu^{\mu\tau}v_2 \\ -\frac{g_1}{\sqrt{2}}v'_\tau & \frac{g_2}{\sqrt{2}}v'_\tau & 0 & r_c^\tau & Y_\nu^{\tau e}v_2 & Y_\nu^{\tau\mu}v_2 & Y_\nu^{\tau\tau}v_2 \end{pmatrix}. \quad (3.5)$$

The matrix $M_{7 \times 7}$ contains the 4×4 block (upper left) of MSSM neutralinos as well as a 3×3 block (bottom right) of gauge-singlet neutrinos and mixing terms between them. The null 3×3 block in $\mathcal{M}_n$ signifies the absence of Majorana mass terms for the left handed neutrinos. The elements of $m_{3 \times 7}$ contain either left handed sneutrino VEVs (v'_i) or Higgs VEVs multiplied by neutrino Yukawa couplings (Y_ν^{ij}), and hence, are of much smaller magnitudes compared to the entries of $M_{7 \times 7}$. This feature ensures a *seesaw*-like structure of $\mathcal{M}_n$.

This 10×10 symmetric matrix $\mathcal{M}_n$ can be diagonalized with a 10×10 unitary matrix N to obtain the physical neutralino states. The mass eigenstates are defined by,

$$\widetilde{\chi}_i^0 = N_{ij} \Psi_j^0, \quad i, j = 1, \dots, 10, \quad (3.6)$$

where N satisfies

$$N^* \mathcal{M}_n N^{-1} = \mathcal{M}_D^0, \quad (3.7)$$

with the diagonal neutralino mass matrix denoted as $\mathcal{M}_D^0$. Seven eigenvalues of this matrix turn out to be heavy, i.e. of the order of the electroweak scale, and thus correspond to the physical neutralinos. The remaining three light eigenvalues correspond to the masses of three SM-neutrinos. One can therefore write eq.(3.7) alternatively as

$$N^* \mathcal{M}_n N^{-1} = \text{diag}(m_{\tilde{\chi}_i^0}, m_j), \quad (3.8)$$

where $i = 1, \dots, 7$ and $j = 1, 2, 3$.

Assuming small R_P violation, it is possible to carry out a perturbative diagonalization of the 10×10 neutralino mass matrix (see [89]), by defining [90] a matrix ξ as

$$\xi = m_{3 \times 7} \cdot M_{7 \times 7}^{-1}. \quad (3.9)$$

If the elements of ξ satisfy $\xi_{ij} \ll 1$, then this can be used as an expansion parameter to get an approximate analytical solution for the matrix N (see eq.(3.7)). A general expression for the elements of ξ with simplified assumptions can be written in the form $\mathcal{A}a_i + \mathcal{B}b_i + \mathcal{C}c_i$, where

$$a_i = Y_\nu^{ii} v_2, \quad c_i = v'_i, \quad b_i = (Y_\nu^{ii} v_1 + 3\lambda v'_i) = (a_i \cot \beta + 3\lambda c_i), \quad (3.10)$$

with $i = e, \mu, \tau \equiv 1, 2, 3$, $\tan \beta = \frac{v_2}{v_1}$ and $\mathcal{A}, \mathcal{B}, \mathcal{C}$ are complicated functions of various parameters of the model. The complete expressions for the elements of ξ are given in appendix B. Here we neglect the subdominant terms $\mathcal{O} \sim \frac{v'^3}{\tilde{m}^3}, \frac{Y_\nu v'^2}{\tilde{m}^2}, \frac{Y_\nu^2 v'}{\tilde{m}}$, where $\tilde{m}$ is the electroweak (or supersymmetry breaking) scale.

The mixing matrix N in leading order in ξ is given by

$$N^* = \begin{pmatrix} \mathcal{N}^* & 0 \\ 0 & U_\nu^T \end{pmatrix} \begin{pmatrix} 1 - \frac{1}{2} \xi^\dagger \xi & \xi^\dagger \\ -\xi & 1 - \frac{1}{2} \xi \xi^\dagger \end{pmatrix}. \quad (3.11)$$

The 10×10 neutralino mass matrix $\mathcal{M}_n$ can approximately be block-diagonalized to the form $\text{diag}(M_{7 \times 7}, M_\nu^{\text{seesaw}})$, by the matrix defined in eq.(3.11). The matrices $\mathcal{N}$ and U_ν , defined in eq.(3.11), are used to diagonalize $M_{7 \times 7}$ and M_ν^{seesaw} in the following manner,

$$\begin{aligned} \mathcal{N}^* M_{7 \times 7} \mathcal{N}^\dagger &= \text{diag}(m_{\tilde{\chi}_i^0}), \\ \mathcal{U}_\nu^T M_\nu^{\text{seesaw}} \mathcal{U}_\nu &= \text{diag}(m_1, m_2, m_3). \end{aligned} \quad (3.12)$$

3.2 Seesaw mechanism and tree level neutrino mass

The effective light neutrino mass matrix M_ν^{seesaw} , arising via the seesaw mechanism in presence of explicit lepton number violation, is in general given by

$$M_\nu^{\text{seesaw}} = -m_{3 \times 7} M_{7 \times 7}^{-1} m_{3 \times 7}^T. \quad (3.13)$$

The eigenvalues and eigenvectors of the 3×3 matrix M_ν^{seesaw} were computed in ref. [73] with the simplifying assumption of a flavour diagonal structure of the neutrino Yukawa

couplings Y_ν^{ij} . Three flavour global neutrino data were fitted with this assumption, and it was observed that all three neutrinos acquire masses even at the tree level.

An approximate analytical expression for the elements of M_ν^{seesaw} at tree level, as obtained in ref. [73], with certain simplifying assumptions is given by

$$(M_\nu^{seesaw})_{ij} = \frac{1}{6\kappa v^c} a_i a_j (1 - 3\delta_{ij}) + \frac{2Av^c}{3\Delta} b_i b_j. \quad (3.14)$$

One can further rewrite eq.(3.14) in an elucidate form given by

$$(M_\nu^{seesaw})_{ij} = f_1 a_i a_j + f_2 c_i c_j + f_3 (a_i c_j + a_j c_i), \quad (3.15)$$

where a_i and c_i are given by eq.(3.10) and

$$\begin{aligned} f_1 &= \frac{1}{6\kappa v^c} (1 - 3\delta_{ij}) + \frac{2Av^c \cot^2 \beta}{3\Delta}, \\ f_2 &= \frac{2A\lambda\mu}{\Delta}, \quad f_3 = \frac{2A\mu \cot \beta}{3\Delta}, \end{aligned} \quad (3.16)$$

with

$$\begin{aligned} \mu &= 3\lambda v^c, \quad A = (\kappa v^{c2} + \lambda v_1 v_2), \\ \Delta &= \lambda^2 (v_1^2 + v_2^2)^2 + 4\lambda\kappa v_1 v_2 v^{c2} - 4\lambda A \mu M, \\ \frac{1}{M} &= \frac{g_1^2}{M_1} + \frac{g_2^2}{M_1}. \end{aligned} \quad (3.17)$$

The reason for recasting eq.(3.14) in terms of a_i and c_i becomes clear when we will discuss our numerical results in section 4. In $(M_\nu^{seesaw})_{ij}$, we neglect the subdominant terms of the order of $\frac{Y_\nu v'^3}{\tilde{m}^2}$, $\frac{Y_\nu^2 v'^2}{\tilde{m}}$ and $Y_\nu^3 v'$. For the convenience of the reader, let us also mention here that we choose λ^i , $(A_\lambda \lambda)^i$, κ^{ijk} , $(A_\kappa \kappa)^{ijk}$ and all soft masses to be *flavour diagonal* and *flavour blind*. The neutrino Yukawa couplings (Y_ν^{ij}) and the corresponding soft terms $(A_\nu Y_\nu)^{ij}$ are, however, chosen to be *flavour diagonal*.

3.3 One loop corrections to the self energies

In the regime of renormalizable quantum field theories, stability of any tree level analysis must be re-examined in the light of radiative corrections. Following this prescription, the results of neutrino masses and mixing will be more robust, once tree level analysis is further improved by incorporating radiative corrections. The radiative corrections may have sizable effect on the neutrino data at one-loop level. Thus, although all three SM neutrinos acquire non-zero masses in the $\mu\nu$ SSM even at the tree level [73], it is interesting to investigate the fate of those tree level masses and mixing when exposed to one-loop corrections. With this in view, in this section we perform a systematic study of the neutrino mass and mixing with all possible one-loop corrections both analytically and numerically. In the subsequent sections, while showing the results of one-loop corrections, we try to explain the deviations (which may or may not be prominent) from the tree level analysis. The complete set of one-loop diagrams are shown in figure1. Before going into the details,

let us discuss certain relevant issues of one-loop correction and renormalization for the neutralino-neutrino sector. The most general one-loop contribution to the unrenormalized neutralino-neutrino two-point function can be expressed as

$$i\Sigma_{\tilde{\chi}^0\tilde{\chi}^0}^{ij}(p) = i\{\not{p}[P_L\Sigma_{ij}^L(p^2) + P_R\Sigma_{ij}^R(p^2)] - [P_L\Pi_{ij}^L(p^2) + P_R\Pi_{ij}^R(p^2)]\}, \quad (3.18)$$

where P_L and P_R are defined in eq.(H.2), $i, j = 1, \dots, 10$ and p is the external momentum. The unrenormalized self-energies Σ and Π depend on the squared external momentum (p^2). The generic self energies $\Sigma_{ij}^{L(R)}$, $\Pi_{ij}^{L(R)}$ of the (Majorana) neutrino must be symmetric in its indices i, j . The resulting one-loop corrected mass matrix using dimensional reduction ($\overline{DR}$) scheme [91] is given by

$$(\mathcal{M}_{\tilde{\chi}^0}^{\text{tree}+1\text{-loop}})^{ij} = m_{\tilde{\chi}^0}(\mu_R)\delta^{ij} + \frac{1}{2} \left(\tilde{\Pi}_{ij}^V(m_i^2) + \tilde{\Pi}_{ij}^V(m_j^2) - m_{\tilde{\chi}_i^0}\tilde{\Sigma}_{ij}^V(m_i^2) - m_{\tilde{\chi}_j^0}\tilde{\Sigma}_{ij}^V(m_j^2) \right), \quad (3.19)$$

with

$$\begin{aligned} \tilde{\Sigma}_{ij}^V &= \frac{1}{2}(\tilde{\Sigma}_{ij}^L + \tilde{\Sigma}_{ij}^R), \\ \tilde{\Pi}_{ij}^V &= \frac{1}{2}(\tilde{\Pi}_{ij}^L + \tilde{\Pi}_{ij}^R). \end{aligned} \quad (3.20)$$

where the tree level neutralino mass ($m_{\tilde{\chi}^0}$) is defined at the renormalization scale μ_R , set at the electroweak scale. Here, the word *neutralino mass* stands for all the *ten* eigenvalues of the 10×10 neutralino mass matrix. The self-energies Σ , Π are also renormalized in the $\overline{DR}$ scheme [91] and denoted by $\tilde{\Sigma}$ and $\tilde{\Pi}$ respectively. The detailed expressions of $\tilde{\Sigma}_{ij}^V$ and $\tilde{\Pi}_{ij}^V$ are given in appendix F.

3.4 Radiative corrections to neutrino mass terms

In this section we consider the effect of radiative corrections to the light neutrino masses. Let us recapitulate some of the earlier work regarding one-loop corrections to the neutralino-neutrino sector. The complete set of radiative corrections to the neutralino mass matrix in the R_P conserving MSSM was discussed in ref. [92], and the leading order neutrino masses has been derived in ref. [6]. One-loop radiative corrections to the neutrino-neutralino mass matrix in the context of a R_P -violating model were calculated in ref. [25] using 't-Hooft-Feynman gauge. In ref. [42], R_ξ gauge has been used to compute the corrections to the neutrino-neutralino mass matrix at one-loop level in an R_P -violating scenario. Neutrino mass generation at the one-loop level in other variants of R_P -violating MSSM has also been addressed in refs. [19, 39, 40, 44–51, 84, 99].

We begin by outlining the strategy of our analysis. We start with a general 10×10 neutralino matrix, with off-diagonal entries as well, which has a *seesaw structure* in the *flavour-basis* (see eq.(3.3)). Schematically, we can rewrite eq.(3.3) as,

$$\mathcal{M}_n = \begin{pmatrix} M_f & m_{D_f}^T \\ m_{D_f} & 0 \end{pmatrix}, \quad (3.21)$$

where the orders of the block matrices are as those indicated in eq.(3.3), and the subscript ' f ' denotes the flavour basis. Here M_f stands for the 7×7 Majorana mass matrix of

the heavy states, while m_{D_f} contains the 3×7 Dirac type masses for the left handed neutrinos. In the next step, instead of utilising the seesaw structure of this matrix to generate the effective light neutrino mass matrix for the three active light neutrino species, we *diagonalize* the entire 10×10 matrix $\mathcal{M}_n$. The diagonal 10×10 matrix M_D^0 thus contains tree level neutralino masses, which we symbolically write as

$$\mathcal{M}_D^0 = \begin{pmatrix} M_m & 0 \\ 0 & m_m \end{pmatrix}, \quad (3.22)$$

where M_m (m_m) are the masses of the heavy states (left handed neutrinos). At this stage we turn on all possible one-loop interactions, so that the 10×10 matrix $\mathcal{M}_D^0$ picks up radiatively generated entries, both diagonal and off-diagonal. The resulting one-loop corrected Lagrangian for the neutralino mass terms, following eq.(3.2), can be written as

$$\mathcal{L}' = -\frac{1}{2} \tilde{\chi}^{0T} (\mathcal{M}_D^0 + \mathcal{M}^1) \tilde{\chi}^0 + \text{H.c.}, \quad (3.23)$$

where $\mathcal{M}^1$ contains the effect of one-loop corrections. The 10×10 matrix $\mathcal{M}_D^0$ is diagonal, but the matrix $\mathcal{M}^1$ is a general symmetric matrix with off diagonal entries.

One can rewrite the above equation, using eqs.(3.6 and 3.7), as

$$\mathcal{L}' = -\frac{1}{2} \Psi^{0T} (\mathcal{M}_n + N^T \mathcal{M}^1 N) \Psi^0 + \text{H.c.}. \quad (3.24)$$

This is nothing but the *one-loop corrected* neutralino mass term in the Lagrangian in the flavour basis. Symbolically,

$$\mathcal{L}' = -\frac{1}{2} \Psi^{0T} \mathcal{M}' \Psi^0 + \text{H.c.}, \quad (3.25)$$

with the 10×10 matrix $\mathcal{M}'$ having the form

$$\mathcal{M}' = \begin{pmatrix} M_f + \Delta M_f & (m_{D_f} + \Delta m_{D_f})^T \\ m_{D_f} + \Delta m_{D_f} & \Delta m_f \end{pmatrix}. \quad (3.26)$$

The quantities ΔM_f and Δm_f stand for one-loop corrections to the heavy neutralino states and light neutrino states respectively, in the flavour basis Ψ^0 . The entity Δm_{D_f} arises because of the off diagonal interactions, i.e. between the heavy neutralinos and the light neutrinos, in the same basis. Note that all of ΔM_f , Δm_{D_f} , Δm_f in the χ_0 basis are given by the second term on the right hand side of eq.(3.19). We suitably transform them into the basis Ψ^0 with the help of neutralino mixing matrix N . Interestingly, the matrix $\mathcal{M}'$ once again possesses a seesaw structure, and one can therefore write down the one-loop corrected effective light neutrino mass matrix as

$$(M^{\nu'})_{\text{eff}} \approx \Delta m_f - (m_{D_f} + \Delta m_{D_f})(M_f + \Delta M_f)^{-1}((m_{D_f} + \Delta m_{D_f})^T). \quad (3.27)$$

Let us now present an approximate form of eq.(3.27). For simplicity, let us begin by assuming the quantities present in eq.(3.27) to be c-numbers (not matrices). In addition, assume $M_f \gg \Delta M_f$ (justified later), so that eq.(3.27) may be written as,

$$(M^{\nu'})_{\text{eff}} \approx \Delta m_f - \delta \times M_f \left\{ \left(\frac{m_{D_f}}{M_f} \right)^2 + 2 \left(\frac{m_{D_f}}{M_f} \right) \left(\frac{\Delta m_{D_f}}{M_f} \right) + \left(\frac{\Delta m_{D_f}}{M_f} \right)^2 \right\}, \quad (3.28)$$

with $\delta = \left(1 - \frac{\Delta M_f}{M_f}\right)$. Now, even when $\Delta m_{D_f} \sim \frac{1}{16\pi^2} m_{D_f}$ and $\Delta M_f \sim \frac{1}{16\pi^2} M_f$, eq.(3.28) looks like

$$(M^{\nu'})_{\text{eff}} \approx \Delta m_f - M_f \left(1 - \frac{1}{16\pi^2}\right) \left\{ \left(\frac{m_{D_f}}{M_f}\right)^2 + \frac{2}{16\pi^2} \left(\frac{m_{D_f}}{M_f}\right)^2 + \frac{1}{256\pi^4} \left(\frac{m_{D_f}}{M_f}\right)^2 \right\}. \quad (3.29)$$

Thus, up to a very good approximation one can rewrite eq.(3.29) as

$$(M^{\nu'})_{\text{eff}} \approx \Delta m_f - M_f \left(\frac{m_{D_f}}{M_f}\right)^2. \quad (3.30)$$

Reimposing the matrix structure and using eq.(3.13), eq.(3.30) can be modified as,

$$(M^{\nu'})_{\text{eff}} \approx \Delta m_f + M_\nu^{\text{seesaw}}. \quad (3.31)$$

The eigenvalues of the 3×3 one-loop corrected neutrino mass matrix $(M^{\nu'})_{\text{eff}}$ thus correspond to one-loop corrected light neutrino masses. In conclusion, it is legitimate to calculate one-loop corrections to the 3×3 light neutrino mass matrix only, and diagonalize it to get the corresponding one-loop corrected mass eigenvalues.

Let us denote the one-loop corrections to the masses of heavy neutralinos and light neutrinos in the basis $\tilde{\chi}^0$ by ΔM and Δm respectively. The one-loop corrections arising from neutralino-neutrino interactions is denoted by Δm_D in the same basis. The tree level neutralino mixing matrix N can then be written as,

$$N = \begin{pmatrix} \tilde{N}_{7 \times 7} & \tilde{N}_{7 \times 3} \\ \tilde{N}_{3 \times 7} & \tilde{N}_{3 \times 3} \end{pmatrix}, \quad (3.32)$$

where the entries of the matrices $\tilde{N}_{7 \times 3}$, $\tilde{N}_{3 \times 7}$ are $\sim \mathcal{O}(m_D^\nu/M_{\tilde{\chi}^0})$, due to very small neutrino-neutralino mixing [93]. The quantities m_D^ν and $M_{\tilde{\chi}^0}$ represent the Dirac mass of neutrino and the Majorana mass of neutralino. From eq.(3.24), it is easy to figure out the relation between Δm and Δm_f as,

$$\Delta m_f = \tilde{N}_{7 \times 3}^T \Delta M \tilde{N}_{7 \times 3} + \tilde{N}_{7 \times 3}^T \Delta m_D^T \tilde{N}_{3 \times 3} + \tilde{N}_{3 \times 3}^T \Delta m_D \tilde{N}_{7 \times 3} + \tilde{N}_{3 \times 3}^T \Delta m \tilde{N}_{3 \times 3}. \quad (3.33)$$

Typically, for a Dirac neutrino, the mass is $\lesssim \mathcal{O}(10^{-4} \text{ GeV})$, while for a neutralino, the mass is $\sim \mathcal{O}(10^2 \text{ GeV})$. This means that the entries of the off-diagonal blocks in eq.(3.32) are $\lesssim \mathcal{O}(10^{-6})$. Therefore, for all practical purposes, one can neglect the first three terms in comparison to the fourth term on the right hand side of eq.(3.33). Thus,

$$\Delta m_f \approx \tilde{N}_{3 \times 3}^T \Delta m \tilde{N}_{3 \times 3}. \quad (3.34)$$

up to a very good approximation. With this in view, our strategy is to compute the one-loop corrections in the $\tilde{\chi}^0$ basis first, and then use eq.(3.34) to obtain the corresponding corrections in the flavour basis. Finally, we diagonalize eq.(3.31) to obtain the one-loop corrected neutrino masses. We have performed all calculations in the 't-Hooft-Feynman

gauge. Let us also note in passing that the form of eq.(3.19) predicts off-diagonal entries ($i \neq j$). The off-diagonal elements are responsible for the mixing between diagonal entries, they become dominant only when $(m_{\tilde{\chi}_i^0} - m_{\tilde{\chi}_j^0}) \lesssim (\frac{\alpha}{4\pi}) \times \text{some electroweak scale mass}$, and then, one can choose $p^2 = \overline{m^2} = (m_{\tilde{\chi}_i^0}^2 + m_{\tilde{\chi}_j^0}^2)/2$ for external momentum [25]. Thus, one can conclude that unless the tree level masses are degenerate, the off-diagonal radiative corrections can be neglected for all practical purposes, when at least one index i or j refers to a heavy states.

The self-energy corrections contain entries of the neutralino mixing matrix N through the couplings $O^{ff'b}$ (see, appendix E). This is because, the self energies $\tilde{\Sigma}_{ij}$ and $\tilde{\Pi}_{ij}$ in general contain products of couplings of the form $O_{i..}^{ff'b} O_{j..}^{ff'b}$. The matrix N , on the other hand, contains the expansion parameter ξ in the leading order (see eq.(3.11)). This observation, together with the help of eq.(B.1), help us to express the effective structure of the one-loop corrected neutrino mass matrix as,

$$[(\mathcal{M}^{\nu'})_{eff}]_{ij} = A_1 a_i a_j + A_2 c_i c_j + A_3 (a_i c_j + a_j c_i), \quad (3.35)$$

where a_i and c_i are given by eq.(3.10) and A_i 's are functions of our model parameters and the Passarino-Veltman functions (B_0, B_1) [94–96] defined in appendix G. The form of the loop corrected mass matrix thus obtained is identical to the tree level one (see, eq.(3.15)) with different coefficients A_1, A_2 and A_3 arising now.

Note that the one-loop diagrams in figure1, contributing to the neutrino mass matrix are very similar to those obtained in bilinear R-parity violating scenario [42–45, 50, 51]. However, it has been pointed out in Ref. [79], that there is a new significant contribution coming from the loops containing the neutral scalar and pseudoscalar with dominant singlet component. This contribution is proportional to the mass-splitting between the singlet scalar and pseudoscalar states [97–99]. The corresponding mass splittings for the doublet sneutrinos are much smaller [79].

3.5 Neutrino mixing

The unitary matrix which diagonalizes the 3×3 light neutrino mass matrix, can be parametrized as [100],

$$\mathcal{U}_\nu = \begin{pmatrix} c_{12}c_{13} & s_{12}c_{13} & s_{13} \\ -s_{12}c_{23} - c_{12}s_{23}s_{13} & c_{12}c_{23} - s_{12}s_{23}s_{13} & s_{23}c_{13} \\ s_{12}s_{23} - c_{12}c_{23}s_{13} & -c_{12}s_{23} - s_{12}c_{23}s_{13} & c_{23}c_{13} \end{pmatrix}, \quad (3.36)$$

provided the charged lepton sector is in the mass-basis (see appendix D). Here $c_{ij} = \cos \theta_{ij}$, $s_{ij} = \sin \theta_{ij}$, and all CP violating phases (Dirac or Majorana) are set to zero. The experimental data on neutrino oscillations [101, 102] indicate that a bilarge pattern of mixing of neutrinos may be preferred, which means that two of the mixing angles must be large. As a first approximation, one can work with $\theta_{23} = 45^\circ$, $\sin \theta_{12} = \frac{1}{\sqrt{3}}$ and

Figure 1: One-loop diagrams contributing to the neutralino masses. The various contributions are arising from (clockwise from top left) (a) neutralino-neutralino-neutral scalar loop, (b) neutralino-neutralino-neutral pseudoscalar loop, (c) neutralino-neutralino- Z_μ^0 loop, (d) neutralino-chargino-charged scalar loop, (e) neutralino-chargino- $W_\mu^\pm$ loop, (f) neutralino-quark-squark loop.

$\theta_{13} \approx 0^\circ$, which is often referred to as the ‘tribimaximal structure’ [103]. Following the above discussions, we can write down the tree level PMNS matrix $\mathcal{U}_\nu$ as,

$$\mathcal{U}_\nu = \tilde{N}_{3 \times 3}^{\prime T}, \quad (3.37)$$

where $\tilde{N}_{3 \times 3}'$ is the matrix that diagonalizes the tree level mass matrix M_ν^{seesaw} (eq.(3.13)).

Similarly, the 3×3 unitary matrix that diagonalizes the one-loop corrected neutrino mass matrix $(M^{\nu'})_{\text{eff}}$ (eq.(3.31)), can be denoted as $\mathcal{U}'_\nu$. Symbolically

$$\mathcal{U}'_\nu{}^{-1} (M^{\nu'})_{\text{eff}} \mathcal{U}'_\nu = \text{diag}(m'_1, m'_2, m'_3), \quad (3.38)$$

with m'_1, m'_2, m'_3 as the three one-loop corrected light neutrino masses. A similar relation for the tree level calculation is given by the second equation of (3.12), with m_i ’s as the tree level neutrino masses.

When we include one-loop corrections, the PMNS matrix $\mathcal{U}'_\nu$ is defined as

$$\mathcal{U}'_\nu = \tilde{N}_{3 \times 3}^{\prime\prime T}, \quad (3.39)$$

where $\tilde{N}_{3 \times 3}^{\prime\prime}$ is the matrix which diagonalizes the one-loop corrected mass matrix $(M^{\nu'})_{\text{eff}}$. The scheme for obtaining the loop-corrected neutrino mixing matrix is shown in figure2.

4. Numerical results of neutrino mass and mixing

In this section we present and explain the results of our numerical analysis. Let us begin with a brief outline of the different well known schemes of light neutrino masses as favoured by experiments. These are (i) The normal hierarchy: $m_1 < m_2 \sim \sqrt{\Delta m_{\text{solar}}^2}$, $m_3 \sim \sqrt{|\Delta m_{\text{atm}}^2|}$, (ii) The inverted hierarchy: $m_1 \approx m_2 \sim \sqrt{|\Delta m_{\text{atm}}^2|}$, $m_3 \ll \sqrt{|\Delta m_{\text{atm}}^2|}$ and (iii)

Flow chart of our calculational approach

Figure 2: Flow chart of the calculational procedure that we have followed in order to calculate the neutrino masses and mixing at the tree level and at one-loop. Here $\mathcal{U}_{PMNS}^{one-loop} = \mathcal{U}'_\nu$, $\mathcal{U}_{PMNS}^{tree} = \mathcal{U}_\nu$, $\mathcal{L}_{flavour-basis}^{tree} = \mathcal{L}_{neutral}^{mass}$, $M_{seesaw}^{tree} = M_\nu^{seesaw}$, $\mathcal{L}^{one-loop} = \mathcal{L}'$ and $M_{seesaw}^{one-loop} = (M^{\nu'})_{eff}$ in the text.

The quasi-degenerate pattern: $m_1 \approx m_2 \approx m_3 \gg \sqrt{|\Delta m_{atm}^2|}$, where m_1, m_2 and m_3 are the three light neutrino masses. Here, $\Delta m_{solar}^2 \equiv m_2^2 - m_1^2$ and $\Delta m_{atm}^2 \equiv m_3^2 - m_2^2$ (or m_1^2) for Normal (inverted) Hierarchy. The possibility of more than one scheme of neutrino masses essentially stems from our lack of knowledge of the signs of the squared mass differences, or the value of individual masses. Such being the case, the numerical analysis must be

subjected to address all the three probable schemes.

The numerical calculations have been performed with the help of a code developed by us in Fortran and the results have been cross-checked using another Mathematica [104] based program we developed. In the code, we keep the left handed sneutrino VEVs (v'), the right handed sneutrino VEVs (v^c) and the neutrino Yukawa couplings (Y_ν) as free input variables, and then scan over the parameter space for a region consistent with the three flavour global neutrino data. For all our numerical analysis we keep the right handed sneutrino VEVs fixed at some chosen values (see table 1). The only exception to this is when we study the correlation of neutrino data with the bilinear R_P -violating parameter $\varepsilon_i = Y_\nu^{ij} v_j^c$. For that particular study, we vary the right handed sneutrino VEVs (consistent with EWSB conditions) within the mass scale -895 GeV to -565 GeV. The table 1 shows our choice of the sample parameters for the numerical analysis. The relation between the gaugino soft masses M_1 and M_2 are assumed to be GUT (grand unified theory) motivated, so that, at the electroweak scale, we have $M_1 : M_2 = 1 : 2$. We choose $M_1 = 110$ GeV.

$\tan\beta$	λ	$A_\lambda\lambda$	κ	$A_\kappa\kappa$	$(A_\nu Y_\nu)^{ii}$	$(m_{\tilde{e}^c}^2)$	v_i^c
10	0.10	$-1\text{TeV} \times \lambda$	0.45	$1\text{TeV} \times \kappa$	$1\text{TeV} \times Y_\nu^{ii}$	300^2 GeV^2	-595 GeV

Table 1: Choice of parameters for numerical analysis consistent with the EWSB conditions.

We scanned the parameter space comprising of the left handed sneutrino VEVs and the neutrino Yukawa couplings extensively and found certain ranges of these parameters appropriate for various hierarchical schemes of the light neutrino masses. In table 2, some sample values for these six parameters for the different mass schemes of neutrinos are given. These values are just for illustration and the parameters were scanned around these numbers to generate the plots shown in this section. The other relevant parameters have values as mentioned in table 1.

While fitting the three flavour global neutrino data, we consider constraints arising from the oscillation data as well as from the non-oscillation data. We probe the effects of these constraints for both tree level and (tree + one-loop) level analyses. The oscillation data constrain the solar and atmospheric mass squared differences, namely, Δm_{solar}^2 and Δm_{atm}^2 , and three neutrino mixing angles θ_{13} , θ_{12} , θ_{23} . The present 3σ limits are [2, 3],

$$\begin{aligned}
7.05 \times 10^{-5} \text{eV}^2 &\leq \Delta m_{solar}^2 \leq 8.34 \times 10^{-5} \text{eV}^2, \\
2.07 \times 10^{-3} \text{eV}^2 &\leq |\Delta m_{atm}^2| \leq 2.75 \times 10^{-3} \text{eV}^2, \\
0.25 &\leq \sin^2 \theta_{12} \leq 0.37, \\
0.36 &\leq \sin^2 \theta_{23} \leq 0.67, \\
\sin^2 \theta_{13} &\leq 0.056.
\end{aligned}
\tag{4.1}$$

The non-oscillation constraints follow from experiments like β decay [105–107], neutrinoless double beta decay ($0\nu\beta\beta$) [108–110] (this is also sensitive to Majorana nature and phases), and from cosmology [111]. Here we set all the Majorana phases to be zero, as we are dealing with a CP -preserving situation.

	$Y_\nu^{ii} \times 10^7$			$v'_i \times 10^5 (\text{GeV})$		
	Y_ν^{11}	Y_ν^{22}	Y_ν^{33}	v'_1	v'_2	v'_3
Normal hierarchy	3.550	5.400	1.650	0.730	10.100	12.450
Inverted hierarchy	12.800	3.300	4.450	8.350	8.680	6.400

Table 2: Values of neutrino Yukawa couplings and left handed sneutrino VEVs, used as sample parameter points for numerical calculations. These are the values around which the corresponding parameters were varied.

The set of non-oscillation constraints are given as,

$$\begin{aligned}
m_\beta &= \sqrt{\sum |\mathcal{U}_{\nu ei}|^2 m_i^2} < 1.80 \text{ eV} \quad (\beta \text{ decay}), \\
0.00 \text{ eV} \leq m_{\beta\beta} &= \left| \sum \mathcal{U}_{\nu ei}^2 m_i \right| \leq 0.25 \text{ eV} \quad (0\nu\beta\beta), \\
\sum m_i &< 1.30 \text{ eV} \quad (\text{cosmology}),
\end{aligned} \tag{4.2}$$

where m_i s are three light neutrino masses, and $\mathcal{U}_{\nu ei}$ s are the elements of the first row of the neutrino mixing matrix (see eq.(3.36)).

4.1 Normal hierarchy

In the normal hierarchical pattern of the three light neutrino masses, the atmospheric and the solar mass squared differences, given by $\Delta m_{atm}^2 = m_3^2 - m_2^2$ and $\Delta m_{solar}^2 = m_2^2 - m_1^2$, are largely governed by the higher mass squared in each case, namely, m_3^2 and m_2^2 , respectively. Before going into the discussion of the variation of the mass-squared values with the model parameter, some general remarks are in order. First of all, note that in eq.(3.10), if we choose v'_i such that $v'_i \gg \frac{Y_\nu^{ii} v_1}{3\lambda}$, then $b_i \approx c_i$ [80]. Thus, for large v'_i , we remind ourselves that in eq.(3.14), the effective light neutrino mass matrix has two types of seesaw structures [73]. The first one is the *ordinary seesaw*, given by

$$m_\nu \sim \frac{a_i^2}{m_{\nu^c}}, \tag{4.3}$$

where $a_i = Y_\nu^{ii} v_2$ represents the *Dirac* mass term for neutrinos, and $m_{\nu^c} = 2\kappa v^c$ stands for the *Majorana* mass term of the right handed neutrino. The second type is called the *gaugino seesaw*, in which the role of the *Dirac* mass terms are played by $g_1 c_i$ and $g_2 c_i$, where g_1, g_2 are the $U(1)$ and the $SU(2)$ gauge couplings respectively and c_i stands for the left handed sneutrino VEV v'_i . The role of the *Majorana* masses are played by the gaugino soft masses M_1, M_2 . This seesaw relation is given as

$$\begin{aligned}
m_\nu &\sim \frac{(g_1 c_i)^2}{M_1} + \frac{(g_2 c_i)^2}{M_2}, \\
&\sim \frac{c_i^2}{M},
\end{aligned} \tag{4.4}$$

where the subscript ' i ' = 1, 2, 3 $\equiv e, \mu, \tau$ and M is the reduced gaugino mass defined by

$$\frac{1}{M} = \frac{g_1^2}{M_1} + \frac{g_2^2}{M_2}. \tag{4.5}$$

M here plays the role of the effective heavy mass provided by the neutral electroweak gaugino sector, and the effect is closely analogous to Type-III seesaw mechanism [112]¹. As discussed after eq.(3.35), when one-loop corrections are added, the neutrino masses are still determined by the quantities a_i^2 and c_i^2 ($\approx b_i^2$ for large v'_i).

Figure 3: Neutrino mass squared values (m_i^2) vs $\frac{c_i^4}{M^2}$ (left panel) and vs $\frac{a_i^4}{m_{\nu c}^2}$ (right panel) plots for the *normal hierarchical* pattern of light neutrino masses, $i = e, \mu, \tau$.

In the subsequent plots, we show the variation of the neutrino squared masses (m_i^2) and the atmospheric and solar mass squared differences with the square of the seesaw parameters $\frac{c_i^2}{M}$ and $\frac{a_i^2}{m_{\nu c}}$. Results are shown for the tree level as well as the one-loop corrected neutrino masses. These plots also demonstrate the importance of one-loop corrections to neutrino masses compared to the tree level results.

¹We thank Anjan Joshipura for pointing this out to one of the authors in a private discussion.

Typical mass spectra are shown in figure 3. Note that a particular model parameter has been varied while the others are fixed at values given in tables 1 and 2. The effective light neutrino mass matrix given in eq.(3.14) suggests that as long as $v'_i \gg \frac{Y_{\nu}^{ii} v_1}{3\lambda}$ and $\kappa \gg \lambda$, the second term on the right hand side of eq.(3.14) dominates over the first term and as a result the heaviest neutrino mass scale (m_3) is controlled mainly by the gaugino seesaw effect. This is because in this limit $b_i \approx c_i$, and, as discussed earlier, a neutrino mass matrix with a structure $(m_\nu)_{ij} \sim \frac{c_i c_j}{M}$ can produce only one non-zero neutrino mass. This feature is evident in figure3, where we see that m_3^2 increases as a function of c_i^4/M^2 . The other two masses are almost insensitive to c_i^2/M . A mild variation to m_2^2 comes from the combined effect of gaugino and ordinary seesaw. On the other hand, the two lighter neutrino mass scales (m_2^2 and m_1^2) are controlled predominantly by the ordinary seesaw parameters a_i^2/m_{ν^c} . This behaviour is observed in the right panel figures of figure3. The heaviest neutrino mass scale is not much affected by the quantities a_i^2/m_{ν^c} .

One can also see from these plots that the inclusion of one-loop corrections, for the chosen values of the soft SUSY breaking parameters, reduces the values of m_2^2 and m_1^2 , while increasing the value of m_3^2 only mildly. This is because, with such a choice, the one-loop corrections cause partial cancellation in the generation of m_1 and m_2 . For the heaviest state, it is just the opposite, since the diagonalization of the tree-level mass matrix already yields a negative mass eigenvalue, on which the loop correction has an additive effect. If, with all other parameters fixed, the signs of λ and A_λ are reversed (leading to a positive μ in the place of a negative one), m_1 , m_2 and m_3 are all found to decrease through loop corrections. A flip in the sign of κ and the corresponding soft breaking terms, on the other hand, causes a rise in all the mass eigenvalues, notably for m_1 and m_2 .

In the light of the discussion above, we now turn to explain the variation of Δm_{atm}^2 and Δm_{solar}^2 with c_i^4/M^2 and $a_i^4/m_{\nu^c}^2$ shown in figure4 and figure5. For our numerical analysis, in order to set the scale of the normal hierarchical spectrum, we choose $m_2|_{max} < 0.011$ eV. The left panel in figure4 shows that Δm_{atm}^2 increases more rapidly with $c_{\mu,\tau}^4/M^2$, whereas the variation with c_e^4/M^2 is much slower as expected from figure3. Similar behaviour is shown for the one-loop corrected Δm_{atm}^2 . The small increase in the one-loop corrected result compared to the tree level one is essentially due to the splitting in m_2^2 value as shown earlier. The variation of Δm_{solar}^2 with c_i^4/M^2 can be explained in a similar manner. Obviously, in this case the one-loop corrected result is smaller compared to the tree level one (see, figure3). However, one should note that Δm_{solar}^2 falls off with c_μ^4/M^2 as opposed to the variation with respect to the other two gaugino seesaw parameters. This is due to the fact that m_2^2 slightly decreases with c_μ^4/M^2 but show a slow increase with respect to c_e^4/M^2 and c_τ^4/M^2 . The dark solid lines in all these figures show the allowed values of various parameters where all the neutrino mass and mixing constraints are satisfied.

The variation of Δm_{atm}^2 and Δm_{solar}^2 with $a_i^4/m_{\nu^c}^2$ in figure5 can be understood in a similar way by looking at the right panel plots of figure3. Δm_{atm}^2 shows a very little increase with $a_{e,\mu}^4/m_{\nu^c}^2$ as expected, whereas the change is more rapid with $a_\tau^4/m_{\nu^c}^2$ for the range of values considered along the x-axis. As in the case of figure4, the solid dark lines correspond to the allowed values of parameters where all the neutrino mass and mixing constraints are satisfied.

Figure 4: Atmospheric and solar mass squared differences (Δm_{atm}^2 , Δm_{solar}^2) vs $\frac{c_i^4}{M^2}$ plots for the *normal hierarchical* pattern of light neutrino masses, $i = e, \mu, \tau$. The full lines are shown for which only the constraints on Δm_{solar}^2 is not within the 3σ limit. The dark coloured portions on these lines are the values of parameters for which all the neutrino constraints are within the 3σ limit. The red (yellow) coloured lines in the plots correspond to the tree (one-loop corrected) regions where all the constraints except Δm_{solar}^2 are within 3σ allowed region. Other parameter choices are discussed in the text.

For higher values of $a_{e,\tau}^4/m_{\nu^c}^2$, m_2^2 increases very slowly with these parameters (see, figure3) and this is reflected in the right panel plots of figure5, where Δm_{solar}^2 shows a very slow variation with $a_{e,\tau}^4/m_{\nu^c}^2$. On the other hand, m_2^2 increases more rapidly with $a_{\mu}^4/m_{\nu^c}^2$, giving rise to a faster variation of Δm_{solar}^2 . The plots of figure5 show that larger values of Yukawa couplings are required in order to satisfy the global three flavour neutrino data, when one considers one-loop corrected neutrino mass matrix. However, there are allowed

Figure 5: Atmospheric and solar mass squared differences (Δm_{atm}^2 , Δm_{solar}^2) vs $a_i^4/m_{\nu^c}^2$ plots for the *normal hierarchical* pattern of light neutrino masses with $i = e, \mu, \tau$. Colour specification is same as described in the context of figure 4. Other parameter choices are discussed in the text.

ranges of the parameters $a_i^4/m_{\nu^c}^2$, where the neutrino data can be satisfied with both tree and one-loop corrected analysis.

We have also considered the variation of light neutrino mass squared differences with the effective bilinear R_P violating parameter, $\varepsilon_i = Y^{ij} v_j^c$. For this particular numerical study we vary both Y_{ν}^{ii} and the right handed sneutrino VEVs v_i^c simultaneously, in the suitable ranges around the values given in table 1 and 2. Δm_{atm}^2 is found to increase with ε_i , whereas the solar mass squared difference decreases with increasing ε_i . The 3σ allowed region for the solar and atmospheric mass squared differences were obtained for the lower values of ε_i s. In addition, we have noticed that the correlations of Δm_{atm}^2 with ε_i is sharper compared to the correlations seen in the case of Δm_{solar}^2 .

Next let us discuss the dependence of Δm_{atm}^2 and Δm_{solar}^2 on two specific model parameters, λ and κ , consistent with EWSB conditions. The loop corrections shift the allowed ranges of κ to lower values with some amount of overlap with the tree level result. On the other hand, the allowed ranges of λ shrinks towards higher values when one-loop corrections are included. These results are shown in figure 6. We note in passing that the mass of the lightest CP-even scalar decreases with increasing λ . For example, $\lambda = 0.15$ can produce a lightest scalar mass of 40 GeV, for suitable choices of other parameters. This happens because with increasing λ , the lightest scalar state picks up more and more right handed sneutrino admixture.

Figure 6: Plots showing the variations of Δm_{atm}^2 , Δm_{solar}^2 with model parameters λ and κ for *normal hierarchy*. Values of all other parameters are given by table 1 and 2. Colour specification is same as described in the context of figure 4. Other parameter choices are discussed in the text.

Finally, we will discuss the $\tan\beta$ dependence of Δm_{atm}^2 and Δm_{solar}^2 . These plots are shown in figure 7. The quantity Δm_{atm}^2 decreases with the increasing values of $\tan\beta$ and nearly saturates for larger values of $\tan\beta$. However, the one-loop corrected result for Δm_{atm}^2 is not much different from that at the tree level for a particular value of $\tan\beta$. On the other hand, the solar mass squared difference initially increases with $\tan\beta$ and for higher values of $\tan\beta$ the variation slows down and tends to saturate. The one-loop corrections result in lower values of Δm_{solar}^2 for a particular $\tan\beta$. The darker and bigger points on both the plots of figure 7 are the allowed values of $\tan\beta$, where all the neutrino experimental data are satisfied. Note that only a very small range of $\tan\beta$ (~ 10 – 14) is allowed. This is a very important observation of this analysis.

Next we will discuss the light neutrino mixing and the effect of one-loop corrections

Figure 7: Δm_{atm}^2 , Δm_{solar}^2 vs $\tan\beta$ plots for the *normal hierarchical* pattern of light neutrino masses. The allowed values of $\tan\beta$ are shown by bold points. Other parameter choices are shown in table 1 and 2.

on the mixing angles. It was shown in ref. [73] that for the normal hierarchical pattern of neutrino masses, when the parameter $b_i \sim a_i$, the neutrino mixing angles θ_{23} and θ_{13} can be written as (with the tree level analysis),

$$\sin^2 \theta_{23} \approx \frac{b_\mu^2}{b_\mu^2 + b_\tau^2}, \quad (4.6)$$

and

$$\sin^2 \theta_{13} \approx \frac{b_e^2}{b_\mu^2 + b_\tau^2}. \quad (4.7)$$

On the other hand, the mixing angle θ_{12} is a much more complicated function of the parameters b_i and a_i and we do not show it here. Now, when $b_i \sim a_i$, we can easily see from eq.(3.10), that

$$v'_i \sim \frac{Y_\nu^{ii} v_1}{3\lambda} (\tan\beta - 1). \quad (4.8)$$

This implies that for $\tan\beta \gg 1$ (recall that the allowed range of $\tan\beta$ is ~ 10 – 14),

$$v'_i \gg \frac{Y_\nu^{ii} v_1}{3\lambda}. \quad (4.9)$$

As we have discussed earlier, for such values of v'_i , the quantities $b_i \approx c_i$. Hence, the mixing angles θ_{23} and θ_{13} can be approximately written as

$$\sin^2 \theta_{23} \approx \frac{c_\mu^2}{c_\mu^2 + c_\tau^2}, \quad (4.10)$$

and

$$\sin^2 \theta_{13} \approx \frac{c_e^2}{c_\mu^2 + c_\tau^2}. \quad (4.11)$$

Naively, one would also expect that $\sin^2 \theta_{12}$ should show some correlation with the quantity c_e^2/c_μ^2 . However, as mentioned earlier, this is a very simple minded expectation since $\sin^2 \theta_{12}$ has a more complicated dependence on the model parameters.

The variation of all three mixing angles with the corresponding parameters are shown in figure 8. Note that in order to generate these plots, we vary only the quantities c_i and all the other parameters are fixed at the values given in tables 1 and 2. We have chosen the range of parameters in such a way that the 3-flavour global neutrino data are satisfied. The mixing angles have been calculated numerically by diagonalizing the neutrino mass matrix in eq.(3.14) and in eq.(3.35). As expected from our approximate analytical expressions, these plots show very nice correlations of the mixing angles θ_{23} and θ_{13} with the relevant parameters as discussed in eqs.(4.10) and (4.11). For example, note that when $c_\mu \approx c_\tau$, $\sin^2 \theta_{23}$ is predicted to be ≈ 0.5 and that is what we observe in the tree level plot in figure 8. However, when one-loop corrections are considered, the value of $\sin^2 \theta_{23}$ is predicted to be somewhat on the lower side of the 3σ allowed region. This can be understood by looking at the left panel plots of figure 4, where one can see that the one-loop corrected results prefer lower values of c_μ^2 and higher values of c_τ^2 . Obviously, this gives smaller $\sin^2 \theta_{23}$. On the other hand, the tree level analysis prefers higher values of c_μ^2 and both lower and higher values of c_τ^2 . This gives rise to large as well as small values of $\sin^2 \theta_{23}$.

Figure 8: Variation of $\sin^2 \theta_{23}$ with $\frac{c_\mu^2}{(c_\mu^2 + c_\tau^2)}$, $\sin^2 \theta_{12}$ with $\frac{c_e^2}{c_\mu^2}$, $\sin^2 \theta_{13}$ with $\frac{c_e^2}{(c_\mu^2 + c_\tau^2)}$ for normal hierarchy of light neutrino masses. Other parameter choices are discussed in the text.

If one looks at the plot of $\sin^2 \theta_{13}$ in figure 8, then it is evident that the amount ν_e flavour in the heaviest state (ν_3) decreases a little bit with the inclusion of one-loop corrections for a fixed value of the quantity $\frac{c_e^2}{(c_\mu^2 + c_\tau^2)}$. Very small $\sin^2 \theta_{13}$ demands $c_e^2 \ll c_\mu^2, c_\tau^2$. This feature is also consistent with the plots in figure 4. The correlation of $\sin^2 \theta_{12}$

with the ratio c_e^2/c_μ^2 is not very sharp as expected from the discussion given above. However, a large θ_{12} mixing angle requires a larger value of this ratio. The effect of one-loop correction is more pronounced in this case and predicts a smaller value of $\sin^2\theta_{12}$ compared to the tree level result. There is no specific correlation of the mixing angles with the quantities a_i^2 and we do not show them here.

4.2 Inverted hierarchy

In this subsection we perform a similar numerical analysis for the inverted hierarchical scheme of three light neutrino masses. Recall that for the inverted hierarchical pattern of light neutrino masses, the absolute values of the mass eigenvalues are such that $m_2 > m_1 \gg m_3$. Thus the solar and the atmospheric mass squared differences are defined as $\Delta m_{atm}^2 = m_1^2 - m_3^2$ and $\Delta m_{solar}^2 = m_2^2 - m_1^2$. In order to generate such a mass pattern, the choices of neutrino Yukawa couplings Y_ν^{ii} and the left-handed sneutrino VEVs v_i' are shown in table 2. However, these are just sample choices and other choices also exist as we will see during the course of this discussion. The choices of other parameters are shown in table 1. The effect of one-loop corrections to the mass eigenvalues are such that the absolute values of masses m_3 and m_1 become smaller whereas m_2 grows in magnitude. This effect of increasing the absolute value of m_2 while decreasing that of m_1 makes it extremely difficult to account for the present 3σ limits on Δm_{solar}^2 .

Typical mass spectra are shown in figure 9. Once again note that a particular model parameter has been varied while the others are fixed at values given in tables 1 and 2. As it is evident from these plots, the masses m_1 and m_3 are controlled mainly by the parameters a_i^2/m_ν^c , whereas the mass m_2 is controlled by the seesaw parameters c_i^2/M though there is a small contribution coming from a_i^2/m_ν^c as well.

Let us now turn our attention to the variation of $|\Delta m_{atm}^2|$ and Δm_{solar}^2 with c_i^4/M^2 and $a_i^4/m_{\nu^c}^2$ shown in figure 10 and figure 11. For our numerical analysis, we have set the scale of m_3 as $|m_3| < 0.011$ eV. The left panel in figure 10 shows that $|\Delta m_{atm}^2|$ increases with $c_{\mu,\tau}^4/M^2$ and decreases with c_e^4/M^2 . This is essentially the behaviour shown by m_1^2 with the variation of c_i^4/M^2 . Similar behaviour is obtained for the one-loop corrected Δm_{atm}^2 . The decrease in the one-loop corrected result compared to the tree level one is due to the splitting in m_1^2 value as shown in figure 9.

The variation of Δm_{solar}^2 with c_i^4/M^2 can be understood in a similar manner by looking at figure 9. As explained earlier, in the case of Δm_{solar}^2 , the one-loop corrected result is larger compared to the tree level one. The range of parameters satisfying all the three flavour global neutrino data are shown by the fewer dark points on the plots. Note that the increase of Δm_{solar}^2 at the one-loop level is such that we do not even see any allowed range of parameters when looking at the variation with respect to $c_{e,\tau}^4/M^2$. Once again, the behaviour of $|\Delta m_{atm}^2|$ and Δm_{solar}^2 with the change in the parameters $a_i^4/m_{\nu^c}^2$ (shown in figure 11) can be explained by looking at the right panel plots of figure 9.

We have also investigated the nature of variation of $|\Delta m_{atm}^2|$ and Δm_{solar}^2 with ε_i^2 , the squared effective bilinear R_P -violating parameters. $|\Delta m_{atm}^2|$ was found to increase with ε_i^2 (the increase is sharper for ε_1^2), whereas Δm_{solar}^2 initially increases very sharply with ε_i^2

Figure 9: Neutrino mass squared values (m_i^2) vs $\frac{c_i^4}{M^2}$ (left panel) and vs $\frac{a_i^4}{m_{\nu c}^2}$ (right panel) plots for the *inverted hierarchical* pattern of light neutrino masses, $i = e, \mu, \tau$.

(particularly for ε_1^2 and ε_2^2) and then becomes flat. In the one-loop corrected results we do not find any range of values for parameters where the neutrino data are satisfied.

The variation of mass squared differences with λ and κ have also been analyzed. The variation of $|\Delta m_{atm}^2|$ and Δm_{solar}^2 with λ and κ are found to be opposite to those of normal hierarchical scenario. The one-loop corrected results do not show any allowed ranges of λ and κ (for the chosen values of other parameters) where the neutrino data can be satisfied.

The $\tan \beta$ dependence of $|\Delta m_{atm}^2|$ and Δm_{solar}^2 is shown in figure12. One can see from these two figures that $|\Delta m_{atm}^2|$ initially increases and then starts decreasing at a value of $\tan \beta$ around 10. On the other hand, Δm_{solar}^2 initially decreases and then starts increasing around the same value of $\tan \beta$. Note that the one-loop corrected result for $|\Delta m_{atm}^2|$ is lower than the corresponding tree level result for $\tan \beta < 10$ whereas the one-loop corrected

Figure 10: Atmospheric and solar mass squared differences ($|\Delta m_{atm}^2|$, Δm_{solar}^2) vs $\frac{c_i^4}{M^2}$ plots for the *inverted hierarchical* pattern of light neutrino masses with $i = e, \mu, \tau$. Colour specification is same as described in the context of figure 4. Choices of other parameters are discussed in the text.

result for Δm_{solar}^2 is lower than the corresponding tree level result for $\tan \beta > 10$. For the chosen values of other parameters we see that the one-loop corrected analysis does not provide any value of $\tan \beta$ where the neutrino data can be satisfied.

We conclude the discussion on inverted hierarchy by addressing the dependence of neutrino mixing angles with the relevant parameters. In figure13 we show the variation of the neutrino mixing angles with the same set of parameters as chosen for the normal hierarchical scenario. We notice that for inverted hierarchy the quantity $\sin^2 \theta_{23}$ decreases with increasing $\frac{c_\mu^2}{(c_\mu^2 + c_\tau^2)}$ which is just opposite to that of the normal hierarchy (see, figure8). Nevertheless, the correlation of $\sin^2 \theta_{23}$ with $\frac{c_\mu^2}{(c_\mu^2 + c_\tau^2)}$ is as sharp as in the case of normal

Figure 11: Atmospheric and solar mass squared differences ($|\Delta m_{atm}^2|$, Δm_{solar}^2) vs $a_i^4/m_{\nu^c}^2$ plots for the *inverted hierarchical* pattern of light neutrino masses with $i = e, \mu, \tau$. Colour specification is same as described in the context of figure 4. Choices of other parameters are discussed in the text.

hierarchy. A similar feature is obtained for the variation with $\frac{a_\mu^2}{(a_\mu^2 + a_\tau^2)}$.

On the other hand, the correlations of $\sin^2 \theta_{12}$ with $\frac{c_e^2}{c_\mu^2}$ and $\frac{a_e^2}{a_\mu^2}$ and the correlations of $\sin^2 \theta_{13}$ with $\frac{c_e^2}{(c_\mu^2 + c_\tau^2)}$ and $\frac{a_e^2}{(a_\mu^2 + a_\tau^2)}$ are not very sharp and we do not show them here. There are allowed values of relevant parameters where all neutrino data can be satisfied. Remember that, for the plots with c_i s, we varied all the c_i s simultaneously, keeping the values of a_i s fixed at the ones determined by the parameters in table 2. Similarly, for the variation of a_i s, the quantities c_i s were fixed. The inclusion of one-loop corrections restrict the allowed values of parameter points significantly compared to the tree level results.

Figure 12: $|\Delta m_{atm}^2|$, Δm_{solar}^2 vs $\tan\beta$ plots for the *inverted hierarchical* pattern of light neutrino masses. Choices of other parameters are discussed in the text.

Figure 13: Variation of $\sin^2 \theta_{23}$ with $\frac{c_\mu^2}{(c_\mu^2 + c_\tau^2)}$ and $\frac{a_\mu^2}{(a_\mu^2 + a_\tau^2)}$ for inverted hierarchy of light neutrino masses. Choices of other parameters are discussed in the text.

4.3 Quasi-degenerate spectra

The discussion on the light neutrino mass spectrum remains incomplete without a note on the so-called “quasi-degenerate” scenario. A truly degenerate scenario of three light neutrino masses is, however, inconsistent with the oscillation data (see eq.(4.1)). Hence, the quasi-degenerate scenario of light neutrino masses is defined in such a way that in this case all the three individual neutrino masses are much larger compared to the atmospheric neutrino mass scale. Mathematically, one writes $m_1 \approx m_2 \approx m_3 \gg \sqrt{|\Delta m_{atm}^2|}$. Obviously, the oscillation data suggest that even in such a situation there must be a mild hierarchy among the degenerate neutrinos.

In this section we have shown that the huge parameter space of $\mu\nu$ SSM always leaves us with enough room to accommodate quasi-degenerate spectrum. For our numerical analysis, we called a set of light neutrino masses to be quasi-degenerate if the lightest among them is greater than 0.1 eV. We choose two sets of sample parameter points which are shown in table 3 (values of other parameters are same as in table 1). For these two sets of neutrino Yukawa couplings (Y_ν^{ii}) and the left-handed sneutrino VEVs (v_i') we observe the following patterns of light neutrino masses at the tree level

- (i) Quasi-degenerate-I: $m_3 \gtrsim m_2 \gtrsim m_1 \gg \sqrt{|\Delta m_{atm}^2|}$,

	$Y_\nu^{ii} \times 10^7$			$v'_i \times 10^5 (\text{GeV})$		
	Y_ν^{11}	Y_ν^{22}	Y_ν^{33}	v'_1	v'_2	v'_3
Quasi-degenerate-I	19.60	19.94	19.99	9.75	10.60	11.83
Quasi-degenerate-II	18.50	18.00	18.00	9.85	10.50	10.10

Table 3: Values of neutrino Yukawa couplings and left handed sneutrino VEVs, used as sample parameter points to obtain quasi-degenerate light neutrino spectrum. Around these values, the corresponding parameters were varied for the plots shown in figure 14.

(ii) Quasi-degenerate-II: $m_2 \gtrsim m_1 \gtrsim m_3 \gg \sqrt{|\Delta m_{atm}^2|}$.

For case (i), we have varied the parameters around the values in table 3 and identified a few extremely fine-tuned points in the parameter space where either the tree level or the one-loop corrected result is consistent with the three flavour global neutrino data. Two representative spectrum as function of $\frac{c_e^4}{M^2}$ and $\frac{a_e^4}{m_{\nu^c}^2}$ are shown in figure 14.

Figure 14: Neutrino mass squared values (m_i^2) vs $\frac{c_e^4}{M^2}$ (left panel) and vs $\frac{a_e^4}{m_{\nu^c}^2}$ (right panel) plots for the *quasi-degenerate* pattern of light neutrino masses.

As mentioned earlier, one can play with the model parameters and obtain a spectrum with a different ordering of masses termed as “Quasi-degenerate-II” in table 3. However, for such an ordering of masses, we found that it was rather impossible to find any region of parameter space where the one-loop corrected result satisfies all the constraints on neutrino masses and mixing. Nevertheless, we must emphasize here that it is not a completely generic conclusion and for other choices of soft SUSY breaking and other parameters it could be possible to have a spectrum like that shown in “Quasi degenerate II” with neutrino constraints satisfied even at the one-loop level. On the other hand, there exists regions where neutrino data are satisfied at the tree level with this ordering of masses.

5. Summary and Conclusion

In this paper, we have performed a systematic study of neutrino masses and mixing in a non-minimal extension of the MSSM, known as $\mu\nu$ SSM, with the complete set of one-loop radiative corrections, over and above the effects from the seesaw mechanism (of Types I and III). A set of right chiral neutrino superfields, introduced in this model provide a solution to

the μ -problem. Lepton number is broken by one $\Delta L = 1$ term comprising the right-chiral neutrinos and the Higgs superfields and another $\Delta L = 3$ term involving only the right chiral neutrinos in the superpotential. The corresponding soft SUSY breaking terms in the scalar potential together with the F-term contribution from the superpotential, induce VEVs of sneutrinos of both right and left chirality. The right chiral neutrinos, together with neutralinos, are instrumental in the generation of light neutrino masses at the tree level.

In [73], where a tree-level analysis of neutrino masses and mixing was carried out, it was shown that tree level masses could be generated in this fashion for all three light neutrinos, even with a flavour diagonal structure of neutrino Yukawa couplings (Y_ν^{ij}). In this work we have improved the analysis with the inclusion of one-loop radiative corrections, for various patterns of light neutrino masses, namely, the normal, inverted and quasi-degenerate spectra. Attempts have been made to identify regions in the SUSY parameter space, which can accommodate the three patterns in turn. Our analysis clearly shows that the multi-dimensional parameter space of $\mu\nu$ SSM leaves enough room to accommodate all the diverse mass hierarchies of the three active light neutrinos.

As a prerequisite of the loop calculation, we have derived the entire set of Feynman rules necessary for our analytical and numerical studies. The set of rules will be of immense importance, should one want to look for signatures of this model at the Large Hadron Collider (LHC), specifically through decays of the new particles of this model into SM particles. Approximate analytical forms of the entries of the expansion matrix ‘ ζ ’ have also been provided including all three generations of right handed neutrinos. A handful of relations within the four-component weak and mass eigenbasis for scalar and fermion fields of $\mu\nu$ SSM have also been worked out.

The correlation of neutrino mass squared differences and mixing angles with relevant model parameters, consistent with the EWSB conditions, have been studied in detail for different mass hierarchies. The allowed regions of the parameter space are found to be rather seriously affected by the one-loop contributions. We have also observed that the globally fitted neutrino data can be accommodated into the $\mu\nu$ SSM for various compositions of the Lightest Supersymmetric Particle (LSP), once one starts playing with the parameters of the model. Although for the present study, we adhered to a Bino dominated LSP scheme, we numerically verified the possibility of having a light right-chiral neutrino (i.e. *singlino*) like LSP, compatible with neutrino data. This, by itself, is an interesting scenario in the sense that the singlino LSP offers a scope to probe the right-handed neutrino mass-scale at the LHC. It would also be interesting to perform an explicit radiative correction to the heavy neutralinos. A dedicated analysis for this is beyond the scope of this paper, and a future publication with comprehensive discussion of all these issues may be well anticipated. In conclusion, one-loop radiative corrections to the neutrino masses and mixing angles for $\mu\nu$ SSM are capable of substantially altering the tree level analysis.

PD is supported through the Gottfried Wilhelm Leibniz Program by the Deutsche Forschungsgemeinschaft (DFG). The work of PD and BM was partially supported by funding available from the Department of Atomic Energy, Government of India, for the Regional Centre for Accelerator-based Particle Physics (RECAPP), Harish-Chandra Research Institute. These two authors also acknowledge the hospitality of the Department of Theoretical Physics of the Indian Association for the Cultivation of Science (IACS), while this work was in progress. PG and SR wish to thank RECAPP for hospitality during a part of the investigation. Computational work for this study was carried out using the cluster computing facility at the Department of Theoretical Physics, IACS.

A. Minimization equations

The minimization equations with respect to the VEVs v^c , v'_i , v_2 , v_1 are given below.

$$2\sum_j u_c^{ij}\zeta^j + \sum_k Y_\nu^{ki} r_c^k v_2^2 + \sum_j (m_{\tilde{\nu}^c}^2)^{jj} v_j^c + \rho^i \eta + \mu \lambda^i v_2^2 + (A_x x)^i = 0, \quad (\text{A.1})$$

$$\sum_j Y_\nu^{ij} v_2 \zeta^j + \sum_j (m_{\tilde{L}}^2)^{jj} v'_j + \sum_j (A_\nu Y_\nu)^{ij} v_j^c v_2 + \gamma_g \xi_v v'_i + r_c^i \eta = 0, \quad (\text{A.2})$$

$$\sum_j \rho^j \zeta^j + \sum_i r_c^{i2} v_2 + \sum_i (A_\nu Y_\nu)^{ij} v'_i v_j^c - \sum_i (A_\lambda \lambda)^i v_i^c v_1 + m_{H_2}^2 v_2 + \mu^2 v_2 - \gamma_g \xi_v v_2 = 0, \quad (\text{A.3})$$

$$-\sum_j \lambda^j v_2 \zeta^j - \mu \sum_j r_c^j v'_j - \sum_i (A_\lambda \lambda)^i v_i^c v_2 + m_{H_1}^2 v_1 + \gamma_g \xi_v v_1 + \mu^2 v_1 = 0, \quad (\text{A.4})$$

where

$$\begin{aligned} (A_x x)^i &= \sum_j (A_\nu Y_\nu)^{ji} v'_j v_2 + \sum_{j,k} (A_\kappa \kappa)^{ijk} v_j^c v_k^c - (A_\lambda \lambda)^i v_1 v_2, \\ r_c^i &= \varepsilon^i = \sum_j Y_\nu^{ij} v_j^c, \quad r^i = \sum_j Y_\nu^{ij} v'_j, \quad u_c^{ij} = \sum_k \kappa^{ijk} v_k^c, \\ \zeta^j &= \sum_i u_c^{ij} v_i^c + r^j v_2 - \lambda^j v_1 v_2, \quad \mu = \sum_i \lambda^i v_i^c, \\ \eta &= \sum_i r_c^i v'_i - \mu v_1, \quad \rho^i = r^i - \lambda^i v_1, \\ \gamma_g &= \frac{1}{4}(g_1^2 + g_2^2), \quad \xi_v = \sum_i v_i'^2 + v_1^2 - v_2^2. \end{aligned} \quad (\text{A.5})$$

In deriving the above equations, it has been assumed that κ^{ijk} , $(A_\kappa \kappa)^{ijk}$, Y_ν^{ij} , $(A_\nu Y_\nu)^{ij}$, $(m_{\tilde{\nu}^c}^2)^{ij}$, $(m_{\tilde{L}}^2)^{ij}$ are all symmetric in i, j, k .

B. Details of expansion matrix ξ

In this appendix the entries of the expansion matrix ξ are given in details

$$\begin{aligned}
\xi_{i1} &\approx \frac{\sqrt{2}g_1\mu m_{\nu^c}^2 M_2 A}{12D} b_i, \\
\xi_{i2} &\approx -\frac{\sqrt{2}g_2\mu m_{\nu^c}^2 M_1 A}{12D} b_i, \\
\xi_{i3} &\approx -\frac{m_{\nu^c}^2 M'}{2D} \left\{ \left(\lambda v_2 v^2 - 4\mu A \frac{M}{v_2} \right) a_i + m_{\nu^c} v_2 v^c b_i - 3\lambda (\lambda v_1 v^2 - 2m_{\nu^c} v^c v_2) c_i \right\}, \\
\xi_{i4} &\approx -\frac{m_{\nu^c}^2 M'}{2D} \left\{ \lambda v_1 v^2 a_i + m_{\nu^c} v_1 v^c b_i + 3\lambda^2 v_2 v^2 c_i \right\}, \\
\xi_{i,4+i} &\approx \frac{m_{\nu^c} M'}{2D} \left\{ 2\lambda \left(\lambda v^4 (1 - \frac{1}{2} \sin^2 2\beta) + \frac{m_{\nu^c}}{2} v^c v^2 \sin 2\beta + A v^2 \sin 2\beta - 4\mu M A \right) a_i - \mu m_{\nu^c} v^2 \cos 2\beta b_i \right\}, \\
\xi_{16} &\approx \xi_{17} \approx -\frac{m_{\nu^c} M'}{2D} \left\{ \lambda (\lambda v^4 - 4\mu M A) a_1 + \frac{\mu m_{\nu^c} v^2}{3} b_1 - 2\lambda \mu m_{\nu^c} v_2^2 c_1 \right\}, \\
\xi_{25} &\approx \xi_{27} \approx -\frac{m_{\nu^c} M'}{2D} \left\{ \lambda (\lambda v^4 - 4\mu M A) a_2 + \frac{\mu m_{\nu^c} v^2}{3} b_2 - 2\lambda \mu m_{\nu^c} v_2^2 c_2 \right\}, \\
\xi_{35} &\approx \xi_{36} \approx -\frac{m_{\nu^c} M'}{2D} \left\{ \lambda (\lambda v^4 - 4\mu M A) a_3 + \frac{\mu m_{\nu^c} v^2}{3} b_3 - 2\lambda \mu m_{\nu^c} v_2^2 c_3 \right\}, \tag{B.1}
\end{aligned}$$

where

$$\begin{aligned}
a_i &= Y_\nu^{ii} v_2, \quad b_i = (Y_\nu^{ii} v_1 + 3\lambda v_i'), \quad c_i = v_i', \\
m_{\nu^c} &= 2\kappa v^c, \quad \mu = 3\lambda v^c, \quad A = (\kappa v^{c^2} + \lambda v_1 v_2), \\
v_2 &= v \sin \beta, \quad v_1 = v \cos \beta, \quad D = \text{Det}[M_{7 \times 7}], \\
\frac{1}{M} &= \frac{g_1^2}{M_1} + \frac{g_2^2}{M_2}, \quad M' = \frac{M_1 M_2}{M}, \tag{B.2}
\end{aligned}$$

with $i = e, \mu, \tau \equiv 1, 2, 3$.

C. Scalar mass squared matrices

The superpotential of the $\mu\nu$ SSM violates R_P through lepton(L) number violation. This allows the Higgses (having zero lepton number) to mix with the sleptons (having non-zero lepton number). Hence, the neutral (both CP -odd and CP -even) and charged Higgs mass squared matrices are enlarged to 8×8 , considering all three slepton generation. The independent entries of the CP -odd, CP -even and the charged scalar mass squared matrices were derived using eqs.(A.3), (A.4), and eq.(A.5). Details of each of these matrix elements were given in ref. [73], hence we do not repeat them here. However, we give the expressions for scalar quark (squark) mass squared matrices.

In this appendix we present the relevant details of various scalar mass squared matrices required for the Feynman rules. The scalar sector of this model have also been addressed in ref. [72, 73, 79, 80].

C.1 CP-odd neutral mass squared matrix

In the weak interaction basis $\Phi_P^T = (H_{1\mathcal{I}}^0, H_{2\mathcal{I}}^0, \tilde{\nu}_{n\mathcal{I}}^c, \tilde{\nu}_{n\mathcal{I}})$, the pseudoscalar mass term in the Lagrangian is of the form

$$\mathcal{L}_{pseudoscalar}^{mass} = \Phi_P^T M_P^2 \Phi_P, \quad (\text{C.1})$$

where M_P^2 is an 8×8 symmetric matrix. The mass eigenvectors are defined as

$$P_\alpha^0 = R_{\alpha\beta}^{P^0} \Phi_{P_\beta}, \quad (\text{C.2})$$

with the diagonal mass matrix

$$(\mathcal{M}_P^{diag})_{\alpha\beta}^2 = R_{\alpha\gamma}^{P^0} M_{P_\gamma\delta}^2 R_{\beta\delta}^{P^0}. \quad (\text{C.3})$$

C.2 CP-even neutral mass squared matrix

In the flavour basis or weak interaction basis $\Phi_S^T = (H_{1\mathcal{R}}^0, H_{2\mathcal{R}}^0, \tilde{\nu}_{n\mathcal{R}}^c, \tilde{\nu}_{n\mathcal{R}})$, the scalar mass term in the Lagrangian is of the form

$$\mathcal{L}_{scalar}^{mass} = \Phi_S^T M_S^2 \Phi_S, \quad (\text{C.4})$$

where M_S^2 is an 8×8 symmetric matrix. The mass eigenvectors are

$$S_\alpha^0 = R_{\alpha\beta}^{S^0} \Phi_{S_\beta}, \quad (\text{C.5})$$

with the diagonal mass matrix

$$(\mathcal{M}_S^{diag})_{\alpha\beta}^2 = R_{\alpha\gamma}^{S^0} M_{S_\gamma\delta}^2 R_{\beta\delta}^{S^0}. \quad (\text{C.6})$$

C.3 Charged scalar mass squared matrix

In the weak basis $\Phi_C^{+T} = (H_1^+, H_2^+, \tilde{e}_{Rn}^+, \tilde{e}_{Ln}^+)$, basis the charged scalar mass term in the Lagrangian is of the form

$$\mathcal{L}_{charged\ scalar}^{mass} = \Phi_C^{-T} M_{C^\pm}^2 \Phi_C^+, \quad (\text{C.7})$$

where $M_{C^\pm}^2$ is an 8×8 symmetric matrix. The mass eigenvectors are

$$S_\alpha^\pm = R_{\alpha\beta}^{S^\pm} \Phi_{C_\beta}^\pm, \quad (\text{C.8})$$

with the diagonal mass matrix

$$(\mathcal{M}_{C^\pm}^{diag})_{\alpha\beta}^2 = R_{\alpha\gamma}^{S^\pm} M_{C_\gamma\delta}^2 R_{\beta\delta}^{S^\pm}. \quad (\text{C.9})$$

One of the eight eigenvalues of the CP-odd scalar and the charged scalar mass squared matrix is zero and corresponds to the neutral and the charged Goldstone boson, respectively. We reiterate that explicit expressions for the independent entries of M_P^2 , M_S^2 and $M_{C^\pm}^2$ are given in ref. [73].

C.4 Scalar quark mass squared matrix

In the weak basis, $\tilde{u}'_i = (\tilde{u}_{L_i}, \tilde{u}_{R_i}^*)$ and $\tilde{d}'_i = (\tilde{d}_{L_i}, \tilde{d}_{R_i}^*)$, we get

$$\mathcal{L}_{squark}^{mass} = \frac{1}{2} \tilde{u}'_i{}^\dagger M_{u_{ij}}^2 \tilde{u}'_j + \frac{1}{2} \tilde{d}'_i{}^\dagger M_{d_{ij}}^2 \tilde{d}'_j, \quad (\text{C.10})$$

where $\tilde{q} = (\tilde{u}', \tilde{d}')$. Explicitly for up and down type squarks $(\tilde{u}, \tilde{d})$, using eq.(A.5) the entries are

$$\begin{aligned} (M_{\tilde{u}}^2)^{L_i L_j} &= (m_{\tilde{Q}}^2)^{ij} + \frac{1}{6} \left(\frac{3g_2^2}{2} - \frac{g_1^2}{2} \right) \xi_v \delta^{ij} + \sum_n Y_u^{in} Y_u^{jn} v_2^2, \\ (M_{\tilde{u}}^2)^{R_i R_j} &= (m_{\tilde{u}^c}^2)^{ij} + \frac{g_1^2}{3} \xi_v \delta^{ij} + \sum_n Y_u^{ni} Y_u^{nj} v_2^2, \\ (M_{\tilde{u}}^2)^{L_i R_j} &= (A_u Y_u)^{ij} v_2 - Y_u^{ij} v_1 \mu + Y_u^{ij} \sum_l r_c^l v_l', \\ (M_{\tilde{u}}^2)^{R_i L_j} &= (M_{\tilde{u}}^2)^{L_j R_i}, \end{aligned} \quad (\text{C.11})$$

and

$$\begin{aligned} (M_{\tilde{d}}^2)^{L_i L_j} &= (m_{\tilde{Q}}^2)^{ij} - \frac{1}{6} \left(\frac{3g_2^2}{2} + \frac{g_1^2}{2} \right) \xi_v \delta^{ij} + \sum_n Y_d^{in} Y_d^{jn} v_1^2, \\ (M_{\tilde{d}}^2)^{R_i R_j} &= (m_{\tilde{d}^c}^2)^{ij} - \frac{g_1^2}{6} \xi_v \delta^{ij} + \sum_n Y_d^{ni} Y_d^{nj} v_1^2, \\ (M_{\tilde{d}}^2)^{L_i R_j} &= (A_d Y_d)^{ij} v_1 - Y_d^{ij} v_2 \mu, \\ (M_{\tilde{d}}^2)^{R_i L_j} &= (M_{\tilde{d}}^2)^{L_j R_i}. \end{aligned} \quad (\text{C.12})$$

For the mass eigenstate $\tilde{\mathbf{q}}_i$ we have

$$\tilde{\mathbf{q}}_i = R_{ij}^{\tilde{\mathbf{q}}} \tilde{\mathbf{q}}_j, \quad (\text{C.13})$$

with the diagonal mass matrix

$$(\mathcal{M}_{\tilde{\mathbf{q}}}^{\text{diag}})^2_{ij} = R_{il}^{\tilde{\mathbf{q}}} M_{q_{lk}}^2 R_{jk}^{\tilde{\mathbf{q}}}. \quad (\text{C.14})$$

D. Charged fermion mass matrix

D.1 Chargino mass matrix

The lepton number (L) violation allows mixing between the MSSM charginos with the charged leptons and thus the chargino mass matrices enhances to 5×5 . The mixing between MSSM charginos and charged leptons are governed by the left handed sneutrino VEVs(v'_i) and neutrino Yukawa couplings. Both of which has to be small in order to satisfy the global neutrino data, thus this R_P violating mixing are very small. The chargino mass matrix for the $\mu\nu$ SMS have been addressed in ref. [72, 73, 79]. In the weak interaction basis defined by

$$\begin{aligned} \Psi^{+T} &= (-i\tilde{\lambda}_2^+, \tilde{H}_2^+, e_R^+, \mu_R^+, \tau_R^+), \\ \Psi^{-T} &= (-i\tilde{\lambda}_2^-, \tilde{H}_1^-, e_L^-, \mu_L^-, \tau_L^-), \end{aligned} \quad (\text{D.1})$$

the charged fermion mass term in the Lagrangian is of the form

$$\mathcal{L}_{charged}^{mass} = -\frac{1}{2} \begin{pmatrix} \Psi^{+T} & \Psi^{-T} \end{pmatrix} \begin{pmatrix} 0_{5 \times 5} & m_{5 \times 5}^T \\ m_{5 \times 5} & 0_{5 \times 5} \end{pmatrix} \begin{pmatrix} \Psi^+ \\ \Psi^- \end{pmatrix}. \quad (\text{D.2})$$

Here for simplicity we assume diagonal form of the charged Yukawa couplings. The matrix $m_{5 \times 5}$ is given by (using eq.(A.5))

$$m_{5 \times 5} = \begin{pmatrix} M_2 & g_2 v_2 & 0 & 0 & 0 \\ g_2 v_1 & \mu & -Y_e^{ee} v'_e & -Y_e^{\mu\mu} v'_\mu & -Y_e^{\tau\tau} v'_\tau \\ g_2 v'_e & -r_c^e & Y_e^{ee} v_1 & 0 & 0 \\ g_2 v'_\mu & -r_c^\mu & 0 & Y_e^{\mu\mu} v_1 & 0 \\ g_2 v'_\tau & -r_c^\tau & 0 & 0 & Y_e^{\tau\tau} v_1 \end{pmatrix}. \quad (\text{D.3})$$

The charged fermion masses are obtained by applying a bi-unitary transformation such that

$$U^* m_{5 \times 5} V^{-1} = \mathcal{M}_D^\pm, \quad (\text{D.4})$$

where U^* and V are two unitary matrices and $\mathcal{M}_D^\pm$ is the diagonal matrix with non-negative entries corresponding to the physical fermion masses. The two-component mass eigenstates are defined by

$$\begin{aligned} \chi_i^+ &= V_{ij} \Psi_j^+, \\ \chi_i^- &= U_{ij} \Psi_j^-, \quad i, j = 1, \dots, 5. \end{aligned} \quad (\text{D.5})$$

Nevertheless, we notice that the 13, 14, and 15 elements of the chargino mass matrix (eq. (D.3)) are vanishing and given the orders of magnitude of various parameters, we also see that the values of the other off-diagonal entries (except for 12 and 21 elements) are very small. This indicates that the physical charged lepton eigenstates will have a very small admixture of charged higgsino and charged gaugino states. So we can very well assume (also verified numerically) that this mixing has very little effect on the mass eigenstates of the charged leptons. Thus, while writing down the neutrino mixing matrix, it will be justified to assume that one is working in the basis where the charged lepton mass matrix is already in the diagonal form.

D.2 Quark mass matrix

The mixing matrices for up and down quarks are 3×3 and they are diagonalized using bi-unitary transformation. Entries of up and down quark mass matrices $m_{3 \times 3}^u$ and $m_{3 \times 3}^d$ are given below

$$\begin{aligned} (m_{3 \times 3}^u)_{ij} &= Y_u^{ij} v_2, \\ (m_{3 \times 3}^d)_{ij} &= Y_d^{ij} v_1. \end{aligned} \quad (\text{D.6})$$

The quark mass matrices are diagonalized as follows

$$\begin{aligned} R_L^{u*} m_{3 \times 3}^u R_R^{u-1} &= \mathcal{M}_U^{diag}, \\ R_L^{d*} m_{3 \times 3}^d R_R^{d-1} &= \mathcal{M}_D^{diag}. \end{aligned} \quad (\text{D.7})$$

E. Feynman rules

In this appendix we will study the relevant Feynman rules required for the calculations of the one-loop contributions to the neutralino masses. Some of the Feynman rules for this model have been derived in ref. [73]. Feynman rules for MSSM are given in ref. [113,114] and in ref. [115,116] for MSSM with singlet superfields. Feynman rules for R_P -violating MSSM were studied in ref. [42]. The required Feynman rules are (using relations of appendix H, shown later) of the form *neutralino-fermion-scalar/gauge boson* and they are listed below.

Neutralino-neutralino-neutral scalar

The Lagrangian using four component spinor notation can be written as

$$\mathcal{L}^{nnh} = -\frac{\tilde{g}}{\sqrt{2}} \tilde{\chi}_i^0 (O_{Lijk}^{nnh} P_L + O_{Rijk}^{nnh} P_R) \tilde{\chi}_j^0 S_k^0, \quad (\text{E.1})$$

where

$$\begin{aligned} \tilde{g} O_{Lijk}^{nnh} = & \eta_j \frac{1}{2} \left[\mathbf{R}_{k1}^{S^0} \left(\frac{g_2}{\sqrt{2}} \mathbf{N}_{i2}^* \mathbf{N}_{j3}^* - \frac{g_1}{\sqrt{2}} \mathbf{N}_{i1}^* \mathbf{N}_{j3}^* - \lambda^m \mathbf{N}_{i4}^* \mathbf{N}_{j,m+4}^* \right) \right. \\ & + \mathbf{R}_{k2}^{S^0} \left(-\frac{g_2}{\sqrt{2}} \mathbf{N}_{i2}^* \mathbf{N}_{j4}^* + \frac{g_1}{\sqrt{2}} \mathbf{N}_{i1}^* \mathbf{N}_{j4}^* - \lambda^m \mathbf{N}_{i3}^* \mathbf{N}_{j,m+4}^* + Y_\nu^{mn} \mathbf{N}_{i,n+4}^* \mathbf{N}_{j,m+7}^* \right) \\ & + \mathbf{R}_{k,m+2}^{S^0} \left(Y_\nu^{mn} \mathbf{N}_{i4}^* \mathbf{N}_{j,n+7}^* - \lambda^m \mathbf{N}_{i3}^* \mathbf{N}_{j4}^* + \kappa^{mnp} \mathbf{N}_{i,n+4}^* \mathbf{N}_{j,p+4}^* \right) \\ & \left. + \mathbf{R}_{k,m+5}^{S^0} \left(\frac{g_2}{\sqrt{2}} \mathbf{N}_{i2}^* \mathbf{N}_{j,m+7}^* - \frac{g_1}{\sqrt{2}} \mathbf{N}_{i1}^* \mathbf{N}_{j,m+7}^* + Y_\nu^{mn} \mathbf{N}_{i4}^* \mathbf{N}_{j,n+4}^* \right) + (i \leftrightarrow j) \right], \end{aligned} \quad (\text{E.2})$$

and

$$O_{Rijk}^{nnh} = (O_{Lijk}^{nnh})^*. \quad (\text{E.3})$$

Neutralino-neutralino-neutral pseudoscalar

The Lagrangian using four component spinor notation can be written as

$$\mathcal{L}^{nna} = -i \frac{\tilde{g}}{\sqrt{2}} \tilde{\chi}_i^0 (O_{Lijk}^{nna} P_L + O_{Rijk}^{nna} P_R) \tilde{\chi}_j^0 P_k^0, \quad (\text{E.4})$$

where

$$\begin{aligned}
\tilde{g}O_{Lijk}^{nna} = & \eta_j \frac{1}{2} \left[\mathbf{R}_{k1}^{P0} \left(-\frac{g_2}{\sqrt{2}} \mathbf{N}_{i2}^* \mathbf{N}_{j3}^* + \frac{g_1}{\sqrt{2}} \mathbf{N}_{i1}^* \mathbf{N}_{j3}^* - \lambda^m \mathbf{N}_{i4}^* \mathbf{N}_{j,m+4}^* \right) \right. \\
& + \mathbf{R}_{k2}^{P0} \left(\frac{g_2}{\sqrt{2}} \mathbf{N}_{i2}^* \mathbf{N}_{j4}^* - \frac{g_1}{\sqrt{2}} \mathbf{N}_{i1}^* \mathbf{N}_{j4}^* - \lambda^m \mathbf{N}_{i3}^* \mathbf{N}_{j,m+4}^* + Y_\nu^{mn} \mathbf{N}_{i,n+4}^* \mathbf{N}_{j,m+7}^* \right) \\
& + \mathbf{R}_{k,m+2}^{P0} (Y_\nu^{mn} \mathbf{N}_{i4}^* \mathbf{N}_{j,n+7}^* - \lambda^m \mathbf{N}_{i3}^* \mathbf{N}_{j4}^* + \kappa^{mnp} \mathbf{N}_{i,n+4}^* \mathbf{N}_{j,p+4}^*) \\
& \left. + \mathbf{R}_{k,m+5}^{P0} \left(-\frac{g_2}{\sqrt{2}} \mathbf{N}_{i2}^* \mathbf{N}_{j,m+7}^* + \frac{g_1}{\sqrt{2}} \mathbf{N}_{i1}^* \mathbf{N}_{j,m+7}^* + Y_\nu^{mn} \mathbf{N}_{i4}^* \mathbf{N}_{j,n+4}^* \right) + (i \leftrightarrow j) \right], \tag{E.5}
\end{aligned}$$

and

$$O_{Rijk}^{nna} = -(O_{Lijk}^{nna})^*. \tag{E.6}$$

Neutralino-neutralino- Z^0

The Lagrangian using four component spinor notation can be written as

$$\mathcal{L}^{nnz} = -\frac{g_2}{2} \tilde{\chi}_i^0 \gamma^\mu (O_{Lij}^{nnz} P_L + O_{Rij}^{nnz} P_R) \tilde{\chi}_j^0 Z_\mu^0, \tag{E.7}$$

where

$$\begin{aligned}
O_{Lij}^{nnz} &= \eta_i \eta_j \frac{1}{2 \cos \theta_W} (\mathbf{N}_{i3} \mathbf{N}_{j3}^* - \mathbf{N}_{i4} \mathbf{N}_{j4}^* + \mathbf{N}_{i,m+7} \mathbf{N}_{j,m+7}^*), \\
O_{Rij}^{nnz} &= \frac{1}{2 \cos \theta_W} (-\mathbf{N}_{i3}^* \mathbf{N}_{j3} + \mathbf{N}_{i4}^* \mathbf{N}_{j4} - \mathbf{N}_{i,m+7}^* \mathbf{N}_{j,m+7}). \tag{E.8}
\end{aligned}$$

Neutralino-chargino-charged scalar

The Lagrangian using four component spinor notation can be written as

$$\mathcal{L}^{ncs} = -\tilde{g} \tilde{\chi}_i (O_{Lijk}^{ncs} P_L + O_{Rijk}^{ncs} P_R) \tilde{\chi}_j^0 S_k^+ - \tilde{g} \tilde{\chi}_i^0 (O_{Lijk}^{ncs} P_L + O_{Rijk}^{ncs} P_R) \tilde{\chi}_j S_k^-, \tag{E.9}$$

where

$$\begin{aligned}
\tilde{g}O_{Lijk}^{ncs} = & \eta_j \left[\mathbf{R}_{k1}^{S^\pm} \left(-\frac{g_2}{\sqrt{2}} \mathbf{U}_{i2}^* \mathbf{N}_{j2}^* - \frac{g_1}{\sqrt{2}} \mathbf{U}_{i2}^* \mathbf{N}_{j1}^* + g_2 \mathbf{U}_{i1}^* \mathbf{N}_{j3}^* \right) \right. \\
& + \mathbf{R}_{k2}^{S^\pm} (\lambda^m \mathbf{U}_{i2}^* \mathbf{N}_{j,m+4}^* - Y_\nu^{mn} \mathbf{U}_{i,m+2}^* \mathbf{N}_{j,n+4}^*) \\
& + \mathbf{R}_{k,m+2}^{S^\pm} (Y_e^{mn} \mathbf{U}_{i,n+2}^* \mathbf{N}_{j3}^* - Y_e^{mn} \mathbf{U}_{i2}^* \mathbf{N}_{j,n+7}^*) \\
& \left. + \mathbf{R}_{k,m+5}^{S^\pm} \left(g_2 \mathbf{U}_{i1}^* \mathbf{N}_{j,m+7}^* - \frac{g_2}{\sqrt{2}} \mathbf{U}_{i,m+2}^* \mathbf{N}_{j2}^* - \frac{g_1}{\sqrt{2}} \mathbf{U}_{i,m+2}^* \mathbf{N}_{j1}^* \right) \right], \\
\tilde{g}O_{Rijk}^{ncs} = & \epsilon_i \left[\mathbf{R}_{k1}^{S^\pm} (\lambda^m \mathbf{V}_{i2} \mathbf{N}_{j,m+4} - Y_e^{mn} \mathbf{V}_{i,n+2} \mathbf{N}_{j,m+7}) \right. \\
& + \mathbf{R}_{k2}^{S^\pm} \left(\frac{g_2}{\sqrt{2}} \mathbf{V}_{i2} \mathbf{N}_{j2} + \frac{g_1}{\sqrt{2}} \mathbf{V}_{i2} \mathbf{N}_{j1} + g_2 \mathbf{V}_{i1} \mathbf{N}_{j4} \right) \\
& + \sqrt{2} g_1 \mathbf{R}_{k,m+2}^{S^\pm} \mathbf{V}_{i,m+2} \mathbf{N}_{j1} \\
& \left. + \mathbf{R}_{k,m+5}^{S^\pm} (Y_e^{mn} \mathbf{V}_{i,n+2} \mathbf{N}_{j3} - Y_\nu^{mn} \mathbf{V}_{i2} \mathbf{N}_{j,n+4}) \right], \tag{E.10}
\end{aligned}$$

and

$$O_{Lijk}^{ncs} = (O_{Rjik}^{cns})^*, \quad O_{Rijk}^{ncs} = (O_{Ljik}^{cns})^*. \quad (\text{E.11})$$

Neutralino-chargino- W

The Lagrangian using four component spinor notation can be written as

$$\mathcal{L}^{ncw} = -g_2 \bar{\tilde{\chi}}_i \gamma^\mu (O_{Lij}^{cnw} P_L + O_{Rij}^{cnw} P_R) \tilde{\chi}_j^0 W_\mu^+ - g_2 \bar{\tilde{\chi}}_i^0 \gamma^\mu (O_{Lij}^{ncw} P_L + O_{Rij}^{ncw} P_R) \tilde{\chi}_j W_\mu^-. \quad (\text{E.12})$$

where

$$\begin{aligned} O_{Lij}^{cnw} &= -\epsilon_i \eta_j \left(\mathbf{V}_{i1} \mathbf{N}_{j2}^* - \frac{1}{\sqrt{2}} \mathbf{V}_{i2} \mathbf{N}_{j4}^* \right), \\ O_{Rij}^{cnw} &= -\mathbf{U}_{i1}^* \mathbf{N}_{j2} - \frac{1}{\sqrt{2}} \mathbf{U}_{i2}^* \mathbf{N}_{j3} - \frac{1}{\sqrt{2}} \mathbf{U}_{i,n+2}^* \mathbf{N}_{j,n+7}, \end{aligned} \quad (\text{E.13})$$

and

$$O_{Lij}^{ncw} = (O_{Lji}^{cnw})^*, \quad O_{Rij}^{ncw} = (O_{Rji}^{cnw})^*. \quad (\text{E.14})$$

The factors η_j and ϵ_i are the proper signs of neutralino and chargino masses [115]. They have values ± 1 .

Neutralino-quark-squark

The Lagrangian using four component spinor notation can be written as

$$\mathcal{L}^{nq\tilde{q}} = -\tilde{g} \bar{q}_i (O_{Lijk}^{qn\tilde{q}} P_L + O_{Rijk}^{qn\tilde{q}} P_R) \tilde{\chi}_j^0 \tilde{q}_k - \tilde{g} \bar{\tilde{\chi}}_i^0 (O_{Lijk}^{nq\tilde{q}} P_L + O_{Rijk}^{nq\tilde{q}} P_R) q_j \tilde{q}_k^*. \quad (\text{E.15})$$

where

$$O_{Lijk}^{qn\tilde{q}} = (O_{Rjik}^{nq\tilde{q}})^*, \quad O_{Rijk}^{qn\tilde{q}} = (O_{Ljik}^{nq\tilde{q}})^*, \quad (\text{E.16})$$

and

$$\begin{aligned} \tilde{g} O_{Lijk}^{nu\tilde{u}} &= \mathbf{R}_{km}^{\tilde{u}} \left(\frac{g_2}{\sqrt{2}} \mathbf{N}_{i2}^* \mathbf{R}_{Ljm}^u + \frac{g_1}{3\sqrt{2}} \mathbf{N}_{i1}^* \mathbf{R}_{Ljm}^u \right) + Y_u^{nm} \mathbf{R}_{k,m+3}^{\tilde{u}} \mathbf{N}_{i4}^* \mathbf{R}_{Ljn}^u, \\ \tilde{g} O_{Rijk}^{nu\tilde{u}} &= Y_u^{mn*} \mathbf{R}_{km}^{\tilde{u}} \mathbf{N}_{i4} R_{Rjn}^{u*} - \frac{4g_1}{3\sqrt{2}} \mathbf{R}_{k,m+3}^{\tilde{u}} \mathbf{N}_{i1} R_{Rjm}^{u*}, \\ \tilde{g} O_{Lijk}^{nd\tilde{d}} &= \mathbf{R}_{km}^{\tilde{d}} \left(-\frac{g_2}{\sqrt{2}} \mathbf{N}_{i2}^* \mathbf{R}_{Ljm}^d + \frac{g_1}{3\sqrt{2}} \mathbf{N}_{i1}^* \mathbf{R}_{Ljm}^d \right) + Y_d^{nm} \mathbf{R}_{k,m+3}^{\tilde{d}} \mathbf{N}_{i3}^* \mathbf{R}_{Ljn}^d, \\ \tilde{g} O_{Rijk}^{nd\tilde{d}} &= Y_d^{mn*} \mathbf{R}_{km}^{\tilde{d}} \mathbf{N}_{i3} R_{Rjn}^{d*} + \frac{2g_1}{3\sqrt{2}} \mathbf{R}_{k,m+3}^{\tilde{d}} \mathbf{N}_{i1} R_{Rjm}^{d*}. \end{aligned} \quad (\text{E.17})$$

F. The $\tilde{\Sigma}_{ij}^V$ and $\tilde{\Pi}_{ij}^V$ function

In this appendix we give the detail expressions for the renormalized self energy functions $\tilde{\Sigma}_{ij}^V$ and $\tilde{\Pi}_{ij}^V$. The net result is

$$\begin{aligned}
\tilde{\Sigma}_{ij}^V = & -\frac{1}{16\pi^2} \left[\frac{\tilde{g}^2}{2} \sum_{r=1}^8 \sum_{k=1}^{10} \left(O_{Lkir}^{nnh} O_{Rjkr}^{nnh} + O_{Ljkr}^{nnh} O_{Rkir}^{nnh} \right) B_1(p^2, m_{\tilde{\chi}_k^0}^2, m_{S_r^0}^2) \right. \\
& - \frac{\tilde{g}^2}{2} \sum_{r=1}^7 \sum_{k=1}^{10} \left(O_{Lkir}^{nna} O_{Rjkr}^{nna} + O_{Ljkr}^{nna} O_{Rkir}^{nna} \right) B_1(p^2, m_{\tilde{\chi}_k^0}^2, m_{P_r^0}^2) \\
& + g_2^2 \sum_{k=1}^{10} \left(O_{Lki}^{nnz} O_{Ljk}^{nnz} + O_{Rki}^{nnz} O_{Rjk}^{nnz} \right) B_1(p^2, m_{\tilde{\chi}_k^0}^2, m_{Z_\mu^0}^2) \\
& + 2g_2^2 \sum_{k=1}^5 \left(O_{Lki}^{cnw} O_{Ljk}^{ncw} + O_{Rki}^{cnw} O_{Rjk}^{ncw} \right) B_1(p^2, m_{\tilde{\chi}_k^\mp}^2, m_{W_\mu^\pm}^2) \\
& + \tilde{g}^2 \sum_{r=1}^7 \sum_{k=1}^5 \left(O_{Lkir}^{cns} O_{Rjkr}^{ncs} + O_{Ljkr}^{ncs} O_{Rkir}^{cns} \right) B_1(p^2, m_{\tilde{\chi}_k^\mp}^2, m_{S_r^\pm}^2) \\
& + 3\tilde{g}^2 \sum_{r=1}^6 \sum_{k=1}^3 \left(O_{Lkir}^{un\tilde{u}} O_{Rjkr}^{nu\tilde{u}} + O_{Ljkr}^{nu\tilde{u}} O_{Rkir}^{un\tilde{u}} \right) B_1(p^2, m_{u_k}^2, m_{\tilde{u}_r}^2) \\
& \left. + 3\tilde{g}^2 \sum_{r=1}^6 \sum_{k=1}^3 \left(O_{Lkir}^{dn\tilde{d}} O_{Rjkr}^{nd\tilde{d}} + O_{Ljkr}^{nd\tilde{d}} O_{Rkir}^{dn\tilde{d}} \right) B_1(p^2, m_{d_k}^2, m_{\tilde{d}_r}^2) \right], \quad (F.1)
\end{aligned}$$

$$\begin{aligned}
\tilde{\Pi}_{ij}^V = & -\frac{1}{16\pi^2} \left[\tilde{g}^2 \sum_{r=1}^8 \sum_{k=1}^{10} \frac{m_{\tilde{\chi}_k^0}}{2} \left(O_{Lkir}^{nnh} O_{Ljkr}^{nnh} + O_{Rkir}^{nnh} O_{Rjkr}^{nnh} \right) B_0(p^2, m_{\tilde{\chi}_k^0}^2, m_{S_r^0}^2) \right. \\
& - \tilde{g}^2 \sum_{r=1}^7 \sum_{k=1}^{10} \frac{m_{\tilde{\chi}_k^0}}{2} \left(O_{Lkir}^{nna} O_{Ljkr}^{nna} + O_{Rkir}^{nna} O_{Rjkr}^{nna} \right) B_0(p^2, m_{\tilde{\chi}_k^0}^2, m_{P_r^0}^2) \\
& - 2g_2^2 \sum_{k=1}^{10} m_{\tilde{\chi}_k^0} \left(O_{Lki}^{nnz} O_{Rjk}^{nnz} + O_{Ljk}^{nnz} O_{Rki}^{nnz} \right) B_0(p^2, m_{\tilde{\chi}_k^0}^2, m_{Z_\mu^0}^2) \\
& - 4g_2^2 \sum_{k=1}^5 m_{\tilde{\chi}_k^\pm} \left(O_{Lki}^{cnw} O_{Rjk}^{ncw} + O_{Rki}^{cnw} O_{Ljk}^{ncw} \right) B_0(p^2, m_{\tilde{\chi}_k^\mp}^2, m_{W_\mu^\pm}^2) \\
& + \tilde{g}^2 \sum_{r=1}^7 \sum_{k=1}^5 m_{\tilde{\chi}_k^\pm} \left(O_{Lkir}^{cns} O_{Ljkr}^{ncs} + O_{Rjkr}^{ncs} O_{Rkir}^{cns} \right) B_0(p^2, m_{\tilde{\chi}_k^\mp}^2, m_{S_r^\pm}^2) \\
& + 3\tilde{g}^2 \sum_{r=1}^6 \sum_{k=1}^3 m_{u_k} \left(O_{Lkir}^{un\tilde{u}} O_{Ljkr}^{nu\tilde{u}} + O_{Rkir}^{nu\tilde{u}} O_{Rjkr}^{un\tilde{u}} \right) B_0(p^2, m_{u_k}^2, m_{\tilde{u}_r}^2) \\
& \left. + 3\tilde{g}^2 \sum_{r=1}^6 \sum_{k=1}^3 m_{d_k} \left(O_{Lkir}^{dn\tilde{d}} O_{Ljkr}^{nd\tilde{d}} + O_{Rkir}^{nd\tilde{d}} O_{Rjkr}^{dn\tilde{d}} \right) B_0(p^2, m_{d_k}^2, m_{\tilde{d}_r}^2) \right]. \quad (F.2)
\end{aligned}$$

Detail expressions for the couplings are given in appendix E. The B_0 , B_1 functions are given in appendix G. The factor 3 appearing in front of the quark-squark loop contributions signifies three variations of quark colour.

G. The B_0 and B_1 function

The B_0 and B_1 functions are Passarino-Veltman [94, 95] functions defined in the notation of [96]

$$\begin{aligned}\frac{i}{16\pi^2}B_0(p^2, m_{f'_k}^2, m_{b_r}^2) &= \mu^{4-D} \int \frac{d^D q}{(2\pi)^D} \frac{1}{(q^2 - m_{f'_k}^2)((q+p)^2 - m_{b_r}^2)}, \\ \frac{i}{16\pi^2}B_\mu(p^2, m_{f'_k}^2, m_{b_r}^2) &= \mu^{4-D} \int \frac{d^D q}{(2\pi)^D} \frac{q_\mu}{(q^2 - m_{f'_k}^2)((q+p)^2 - m_{b_r}^2)}, \\ B_\mu(p^2, m_{f'_k}^2, m_{b_r}^2) &= p_\mu B_1(p^2, m_{f'_k}^2, m_{b_r}^2).\end{aligned}\tag{G.1}$$

H. Some Useful Relations

Fermionic sector

For neutralinos the following relations between mass and weak eigenstates are very useful

$$\begin{aligned}P_L \tilde{B}^0 &= P_L N_{i1}^* \tilde{\chi}_i^0, & P_L \tilde{W}_3^0 &= P_L N_{i2}^* \tilde{\chi}_i^0, & P_L \tilde{H}_j &= P_L N_{i,j+2}^* \tilde{\chi}_i^0, \\ P_L \nu_k &= P_L N_{i,k+7}^* \tilde{\chi}_i^0, & P_L \nu_k^c &= P_L N_{i,k+4}^* \tilde{\chi}_i^0, \\ P_R \tilde{B}^0 &= P_R N_{i1} \tilde{\chi}_i^0, & P_R \tilde{W}_3^0 &= P_R N_{i2} \tilde{\chi}_i^0, & P_R \tilde{H}_j &= P_R N_{i,j+2}, \\ P_R \nu_k &= P_R N_{i,k+7} \tilde{\chi}_i^0, & P_R \nu_k^c &= P_R N_{i,k+4} \tilde{\chi}_i^0, \\ \text{where } j &= 1, 2 \quad \text{and} \quad k = 1, 2, 3,\end{aligned}\tag{H.1}$$

with i varies from 1 to 10 and

$$P_L = \left(\frac{1 - \gamma^5}{2} \right), \quad P_R = \left(\frac{1 + \gamma^5}{2} \right).\tag{H.2}$$

In terms of the four component spinors χ_i for charginos, the following relations between mass and weak eigenstates are very useful.

$$\begin{aligned}P_L \tilde{W} &= P_L V_{i1}^* \tilde{\chi}_i, & P_L \tilde{H} &= P_L V_{i2}^* \tilde{\chi}_i, & P_L l_k &= P_L U_{i,k+2}^* \tilde{\chi}_i^c, \\ P_R \tilde{W} &= P_R U_{i1} \tilde{\chi}_i, & P_R \tilde{H} &= P_R U_{i2} \tilde{\chi}_i, & P_R l_k &= P_R V_{i,k+2} \tilde{\chi}_i^c, \\ P_L \tilde{W}^c &= P_L U_{i1}^* \tilde{\chi}_i^c, & P_L \tilde{H}^c &= P_L U_{i2}^* \tilde{\chi}_i^c, & P_L l_k^c &= P_L V_{i,k+2}^* \tilde{\chi}_i, \\ P_R \tilde{W}^c &= P_R V_{i1} \tilde{\chi}_i^c, & P_R \tilde{H}^c &= P_R V_{i2} \tilde{\chi}_i^c, & P_R l_k^c &= P_R U_{i,k+2} \tilde{\chi}_i,\end{aligned}\tag{H.3}$$

where $k = 1, 2, 3$, and i varies from 1 to 5. The last six relations are for the charge-conjugated fields.

The four component neutralino, chargino and charge conjugated chargino spinors are respectively defined as

$$\tilde{\chi}_i^0 = \begin{pmatrix} \chi_i^0 \\ \chi_i^0 \end{pmatrix}, \quad \tilde{\chi}_i = \begin{pmatrix} \chi_i^+ \\ \chi_i^- \end{pmatrix}, \quad \tilde{\chi}_i^c = \begin{pmatrix} \chi_i^- \\ \chi_i^+ \end{pmatrix}, \quad (\text{H.4})$$

where χ_i^0 and $\chi_i^\pm$ are two component neutral and charged spinors, respectively.

Scalar sector

The relations between weak and mass eigenstates for neutral scalar, neutral pseudoscalar and charged scalar are given by eqs.(C.2), (C.5), and (C.8).
